

Exploring the Impact of Human Psychology and Counseling in Enhancing User Experience and Mental Well-being. (Within the ICT Industry through Web Technology)

By

P.K. Imashi Sandeepika Bandara

C 38874

A Dissertation

Submitted to the Department of Psychology

IMBS Green Campus

In Fulfillment of the Requirements

For the Bachelor of Arts in Psychology Degree Programme

Offered by IIC University of Technology, Cambodia

Under the Supervision of Ms. Romesha Dayananda

November 2024

Declaration by the Candidate

I hereby declare that the thesis titled: “[**Exploring the Impact of Human Psychology and Counseling in Enhancing User Experience and Mental Well-being. (Within the ICT Industry through Web Technology)**]” Submitted to **IMBS Green Campus** in partial fulfillment of the requirements for the degree of **Bachelor of Psychology**, is my original work. This thesis has not been submitted previously to any other institution for any academic qualification or certification. I further declare that all sources of information used in this research have been acknowledged appropriately.

Name of Candidate: P.K. Imashi Sandeepika Bandara

Registration Number: C 38874

Date :

Signature :

Certification by the Research Supervisor

I certify that the work presented in this thesis, **“Exploring the Impact of Human Psychology and Counseling in Enhancing User Experience and Mental Well-being. (Within the ICT Industry through Web Technology)”**, was carried out under my supervision and guidance. The thesis meets the required academic standards and is suitable for submission for the degree of **Bachelor of Psychology**.

Name of Research Supervisor: Ms. Romesha Dayananda

Designation :

Date :

Signature :

Approval by Head of the Department

This thesis, “[Exploring the Impact of Human Psychology and Counseling in Enhancing User Experience and Mental Well-being. (Within the ICT Industry through Web Technology)]”, has been reviewed and approved for submission to the Department of Psychology, **IMBS Green Campus**.

Name :

Designation :

Date :

Signature :

Endorsement by the Module Lecturer

I endorse that the thesis, **“Exploring the Impact of Human Psychology and Counseling in Enhancing User Experience and Mental Well-being. (Within the ICT Industry through Web Technology)”**, has been conducted and compiled in accordance with the academic guidelines and meets the criteria set for the **Bachelor of Psychology** program.

Name of Module Lecturer :

Designation :

Date :

Signature :

Acknowledgements

I want to sincerely thank everyone who has helped and advised me during my research process, which has enabled me to complete this thesis.

I want to start by sincerely thanking my supervisors for their excellent advice, helpful criticism, and support during the study process. Their knowledge and guidance have greatly influenced this work.

I am incredibly appreciative of the university professors who so kindly contributed their expertise and views, assisting me in honing my concepts and offering academic support when required.

A particular thank you is extended to the seniors who were final-year interns, whose interviews and conversations provided insightful opinions and important input for our research. The quality of this research has been enhanced by their willingness to share their experiences.

I would also like to acknowledge the contributions of the demo instructors and ICT company technicians who provided practical insights and shared their expertise in the field. Their input has been instrumental in grounding this work in real-world applications.

Finally, I am sincerely thankful to my family, friends, and colleagues for their unwavering support, understanding, and encouragement throughout this journey. Your belief in me has been my greatest source of strength.

This work would not have been possible without the collective efforts and contributions of all these individuals and institutions. Thank you for being an integral part of this academic milestone.

Abstract

There is a lot of opportunity for improving user experience (UX) and mental health in the ICT sector at the nexus of web technology, counseling, and human psychology. This study investigates how psychological concepts and counseling methods can be applied to create user-centered digital spaces that put emotional well-being and functionality first. The study looks at how concepts like digital empathy, emotive design, and cognitive load theory might reduce stress and promote constructive interactions with technology. It also looks into how counseling techniques like guided decision-making and customized feedback might be incorporated to make platforms that are easy to use and emotionally encouraging.

In order to discover existing gaps in web technology designs that contribute to annoyance, anxiety, and digital weariness, the research uses qualitative approaches, such as interviews with ICT professionals and users. It also suggests a framework for integrating human-centered psychological concepts into ICT development procedures, with a focus on doable strategies to lessen digital fatigue and raise user pleasure.

The goal of this study is to persuade the ICT industry to embrace more humane and cognitively uplifting practices by addressing the psychological aspects of user interactions. Developers, UX designers, and legislators will gain from the findings since they offer practical advice for building inclusive technologies that improve user engagement and mental health in a world that is becoming more and more digital.

Chapter 01. Introduction

1.1 Background and Context

The relationship between information and communication technology (ICT) and human psychology is more important than ever in the quickly evolving digital society we live in today. With web technologies becoming essential to interactions in the personal, professional, and educational spheres, the ICT sector is revolutionizing everyday life. The importance of user experience (UX) in the development of digital platforms has grown as these platforms have developed. This change is a reflection of the increasing significance of user engagement with digital platforms, which is impacted by psychological, emotional, and cognitive variables. Understanding human psychology, which provides insights into user behavior, decision-making, and emotional responses when navigating these digital landscapes, is at the core of this interaction.

Users' experiences with technology are influenced by psychological processes as attention, perception, memory, and emotional states. With individuals depending more and more on webbased technology for both personal and professional purposes, the influence of these procedures is particularly significant. Given this, user experience (UX) design must go beyond usability and functional efficiency to take emotional and mental health into account. The development of web technologies has changed significantly as a result of this increased awareness, with a greater focus now being placed on developing friendly environments that promote mental health and increase user engagement.

The incorporation of psychological concepts and counseling approaches into UX design is still a largely unexplored field in ICT, despite the importance of concentrating on technology functionality and performance. The psychological effects, including stress, cognitive overload, and emotional tiredness, become more noticeable as people use digital platforms more frequently. An emerging area in the creation of ICT products that put functionality and mental health first is the understanding of these psychological consequences and the use of counseling strategies to treat them.

1.2 Research Problem

The psychological and emotional detachment that users frequently encounter when interacting with digital platforms is the main research issue of this study. Even though web technologies are widely used, many ICT solutions prioritize efficiency and usability over the psychological demands of users. Anxiety, frustration, and cognitive exhaustion result from this, which may lower user engagement and satisfaction. Because of this, users often experience stress, emotional tiredness, and digital burnout-problems that standard web development techniques hardly ever address.

Furthermore, there is still little use of counseling approaches in the web technology design process. By encouraging empathy, compassion, and emotional support via digital platforms, counseling which focuses on mental health and emotional well-being has a great deal of potential to improve user experience. Nonetheless, there is a clear discrepancy between the design of ICT tools and the psychological components of human connection. In order to mitigate the detrimental psychological impacts of prolonged digital engagement, the study challenge aims to investigate how web technology design might incorporate human psychology and counseling strategies to enhance user experience and promote mental well-being.

1.3 Significance of the Study

This study is very important from a theoretical and practical standpoint. The study adds to the expanding corpus of research on the psychological effects of digital technology by bridging the gap between human psychology, counseling, and ICT design. It offers insightful information about how web developers and UX designers might make digital spaces that are more sympathetic and psychologically encouraging.

Given the growing worries about digital burnout, anxiety, and mental health problems associated with excessive screen time and digital tool usage, it is especially appropriate to incorporate counseling techniques into web technology development. The results of the study can help ICT experts create solutions that support users' emotional health in addition to meeting functional and usability requirements. Digital ecosystems that are more user-friendly, sustainable, and supportive may result from this.

Furthermore, the study provides useful advantages for end users, who will profit from more psychologically sensitive and emotionally aware devices. This research attempts to promote

healthier user engagement, lessen stress and weariness, and increase overall user happiness by improving the mental health support built into online technologies. The research findings have ramifications for educators and policymakers, who can utilize them to shape ICT training standards and recommendations that put user mental health first.

1.4 Research Objectives

This study's main goal is to investigate how human psychology and counseling may improve user experience and mental health in the ICT sector by using web technologies. The following particular goals serve as the research's compass in order to accomplish this overall goal:

Examining Psychological Theories and Concepts in Web Technologies: This goal is to comprehend the present applications of psychological theories and concepts to web technologies, including behaviorism, cognitive load theory, and emotive design. It will investigate the ways in which these ideas affect overall satisfaction, emotional involvement, and user experience.

ICT Development and Counseling approaches: This sub-objective looks at how to best integrate counseling approaches into ICT tool design and development. These strategies can reduce stress and cognitive overload by offering emotional support, empathy, and guided decision-making, resulting in a more supportive and balanced user experience.

Finding Psychological Flaws in Current ICT products: Finding psychological flaws in current ICT products that cause user annoyance, worry, or mental fatigue is another important goal. This study intends to identify areas in which technology falls short of psychological needs in order to suggest enhancements that can improve mental health.

Creating a Structure for Combining Counseling and Psychological Methods: Developing a methodical framework that incorporates human-centered psychological and counseling principles into the ICT development process is the main goal of this purpose. The framework will serve as a guide for developers and designers as they create digital platforms that include mental health in addition to functionality and usability.

Assessing the Impact of Psychologically Informed online Technologies: The ultimate goal is to determine how well online technologies that integrate counseling and psychology concepts enhance user experience and promote mental wellness. Case studies, user testing, and feedback

analysis will all be used to assess how effectively these technologies work to lower digital stress and improve general wellbeing.

1.5 Research Hypothesis

The study's goals and setting support the idea that incorporating counseling methods and human psychology into online technology design improves user experience and mental health. In particular, it is predicted that web platforms created with psychological concepts and counseling assistance will lessen digital stress, ease cognitive overload, and enhance emotional engagement, creating a more fulfilling and psychologically healing online space.

1.6 Importance of the Research

The results of this study will have a significant impact on how digital tools are developed in the future. This study promotes a more sympathetic approach to web creation that takes users' emotional and mental health needs into account by integrating psychological concepts into ICT design. In addition to reducing the negative psychological impacts of technology use, this strategy can encourage a more positive, interesting, and encouraging online experience. In the end, the findings can contribute to a more comprehensive approach to digital well-being by assisting ICT professionals in developing solutions that promote emotional resilience, lessen digital fatigue, and increase user happiness.

Furthermore, this study is important for the larger field of digital mental health. Addressing the effects of extended use of digital platforms on mental health is crucial as these platforms become more and more integrated into daily life. A proactive response to the problems presented by the expanding digital world can be found by incorporating counseling approaches into ICT design, which can be crucial in reducing the detrimental psychological effects of digital involvement.

Chapter 02. Literature Review

2.1 Introduction

The Information and Communication Technology (ICT) sector's rapid advancement of web technology has brought about a significant shift in people's interactions with digital platforms. While increasing productivity and connectivity are benefits of these innovations, user experience and mental health concerns have also been raised. This study, which emphasizes the ways in which psychological understanding can enhance user experience and assist mental health in digital settings, relies heavily on human psychology and therapy to address these concerns. By fusing counselling concepts with online technology, web designers can produce more compassionate and approachable user interfaces that cater to users' psychological needs, reducing stress and increasing overall pleasure. This project aims to investigate the consequences of such integration with a focus on how understanding user behavior, emotional reactions, and cognitive processes might lead to the design of more supportive digital environments. In the conclusion, this research seeks to demonstrate how, by prioritizing mental health and making use of psychological insights, the ICT industry can foster healthier, more positive connections with technology and contribute to the creation of a more inclusive and mentally supportive digital environment.

2.2 Previous Study

2.2.1 Human psychology

Human psychology is the scientific study of the mind and behavior, encompassing various aspects such as cognition, emotion, motivation, development, personality, and social interactions. It seeks to understand how individuals perceive, think, feel, and act, both as individuals and within groups. The field of psychology is vast, with subfields including clinical psychology, cognitive psychology, developmental psychology, social psychology, and neuropsychology, among others. A article defining it as the study of behavior and the mind by scientists. It discusses the history, subfields, and uses of psychology while highlighting how crucial it is to comprehending human behavior, feelings, and mental processes (McLeod, 2023 oct). The scientific study of the mind and behavior, focusing on its four main goals-describing, explaining, predicting, and changing behavior. It illustrates how these goals are used in various contexts, from clinical settings to everyday life

(Cherry, The Major Goals of Psychology, 2022 Oct). the development and history of psychology, beginning with its philosophical and physiological foundations. It examines many schools of thought that have influenced the area, including as behaviorism, structuralism, and functionalism, and it talks about influential people like Wilhelm Wundt (Cherry, The Origins of Psychology, 2024 july).

Psychology is defined further as the scientific study of the mind and behavior, looking at how different elements like culture, biology, and environment influence how people think and behave. It also discusses the various branches of psychology, such as social, cognitive, and clinical psychology (Colman, 2024). An overview of psychology is given in another article, along with an explanation of its significance in comprehending mental processes and behavior in people. It provides a thorough introduction for newcomers by covering the field's history, key theories, and current applications (Dotdash, 2024). Psychology is defined by the American Psychological Association as the study of the mind and behavior, with practical applications found in a variety of fields, including business, education, and health. It also emphasizes how crucial psychology is to tackling societal issues and raising standards of living (Psychology Subfields, 2023).

2.2.2 Counselling

The professional practice of counselling uses psychological concepts to assist individuals, couples, families, and groups in achieving mental health, emotional stability, and personal development. In a collaborative partnership, the counsellor and the client work through a variety of challenges as the counsellor offers the client support, direction, and techniques. Considering psychology as a broad specialty within professional psychology, our goal is to improve mental health and wellbeing for individuals by applying psychological concepts. It places a strong emphasis on a clientcentered, holistic method of studying and treating psychological problems that incorporates social context and culture (CPA, 2009 Nov). Psychology, with a focus on its use in psychotherapy, is the scientific study of the mind and behavior. In order to give successful therapy, it outlines the responsibility of psychologists in comprehending mental processes and behaviors (Understanding psychotherapy & how it works, 2023). The article defines psychology as the study of behavior and mental processes and explains how it serves as the basis for counselling techniques. It demonstrates how counselling psychology applies this understanding to assist clients in resolving a range of life's obstacles (Vanja Orlans, 2012 June)

This paper offers a thorough introduction to counselling psychology, stressing the application of psychological concepts in the treatment of mental health and wellbeing. It also covers the significance of understanding people in the context of their social and cultural backgrounds (CPA, 2009 Nov). Furthermore, characterizes psychology as the study of behavior and mental processes, with an emphasis on the ways in which counselling psychologists use this understanding to empower people and enhance their psychological functioning (Stanley, 2013). In addition, psychology in the counselling environment emphasizes the application of psychological ideas and techniques to advance mental health and wellbeing. It talks about the function of counselling psychologists in different contexts (A Career in Counselling Psychology, 2014).

2.2.3 Human Psychology and Counselling in the ICT Industry

A growing need to address the psychological effects of technology on users is shown in the ICT industry's integration of human psychology and counselling. ICT technologies, which serve a variety of groups, including those living in remote places, provide scalable and easily available psychological support solutions. Examples of these tools are mental health apps and online treatment. Nevertheless, there are drawbacks to this change, such as preserving the standard of interpersonal communication and protecting personal information. Through the use of psychological concepts, ICT can improve user experiences, lower stress levels, and promote wellbeing. This multidisciplinary approach maximizes the efficacy and usability of ICT applications while simultaneously improving mental health outcomes. This essay examines how ICT tools—like telemedicine and online treatment platforms—are changing the counselling landscape. It addresses issues like data privacy and the possible loss of personal connection while also highlighting the advantages, such as improved accessibility and convenience.

According to the article, combining ICT with conventional counselling techniques can improve mental health in general (Editorial, The Role of ICT in Counseling: Opportunities and Challenges, 2024). In order to better understand how ICT was used during the COVID-19 epidemic, this study looks at how social connectivity and anxiety were affected. The results indicate that social relationships can be strengthened and anxiety can be decreased through balanced ICT use, particularly when it is in line with users' psychological needs. The study emphasizes how crucial proper ICT use is to preserving mental health (Rini Rachmawati, 2021 June). The increasing use of ICT in providing mental health services, such as prevention and therapy, is covered in this

article. It discusses ICT-based interventions' efficacy, viability, and constraints while highlighting how these tools could increase access to mental health care, especially for marginalized groups (Humanas, 2021). The opinions of mental health counsellors regarding the use of technology in their sessions are examined in this study. It draws attention to the benefits of ICT, like the capacity to reach clients in far-off places, but it also exposes issues with the impersonality of online interactions. The essay advocates for a well-rounded strategy in which technology enhances human connection but does not take its place (S, 2019 jan). The psychological impacts of ICT adoption in the workplace, namely in the ICT industry, are the subject of this study. It talks about how using technology can increase output but can lead to stress and burnout. According to the article, incorporating counselling and psychological support into ICT practices at work can lessen unfavorable effects (Humanas, 2021). The growth of telemedicine in counselling is examined in this article, with special attention on the COVID-19 epidemic. It draws attention to the transition from in-person to virtual sessions and looks at the ramifications for counsellors and clients. The article's conclusion is that, when applied skillfully, telehealth can enhance conventional counselling techniques and lead to better mental health outcomes (Ma.Regina M. hachanova, 2013 Aug).

2.2.4 Enhancing User Experience & Mental Well-being

The idea of "Enhancing User Experience & Mental Well-being" is creating and utilizing technology in ways that support mental health in general as well as positive psychological states and functional demands. Today's digital age involves constant connection with technology; thus user experience (UX) encompasses more than just usability and efficiency—it also takes into account psychological and emotional factors. Improving user experience (UX) involves designing user interfaces, goods, and services that are pleasurable, easy to use, and promote mental health in users. The seamless integration of user experience and mental well-being transforms technology from a mere tool to an enriching tool that enhances life (Christian, 2023 June)

Many techniques based on psychology and human-centered design are used by designers and developers to improve user experience and mental health. These include utilizing soothing color schemes and patterns, designing user-friendly interfaces that lessen cognitive burden, and adding elements that promote pleasant emotions and behavior. For example, mindfulness applications are made with straightforward, calming user interfaces that lead users through breathing exercises and

enhance mental health. Furthermore, users' overall experience and emotional pleasure can be improved via personalized experiences, in which technology adjusts to suit individual tastes and needs. This allows users to feel understood and appreciated (Curtis, The Role of UX Design in Mental Health Web Development, 2023 Apr). Persuasive design is one strategy that can be used to improve both user experience and mental health since it uses psychological concepts to promote constructive user behavior. This may be sending out alerts to users to take breaks, motivating them to exercise, or even using technology to encourage social engagement. Technology can be proactive in preserving and enhancing mental health by incorporating these mild prods into the user experience. Empathetic design, in which technology is developed with a thorough awareness of the user's emotional and psychological needs, is an additional tactic. This entails predicting and reacting in real-time to users' emotional states, such as stress or irritation, in addition to meeting functional objectives (Curtis, Designing for Mental Health & Well-being: The Role UX Plays in it All, 2023 Apr) .

The benefits of improving mental health and user experience can be profound and far-reaching. There is an increase in user pleasure, engagement, and loyalty when they use technology that promotes mental wellness. This beneficial relationship can lower tension and anxiety, boost output, and improve decision-making. Employees that use tools created with their mental health in mind at work, for instance, are probably going to feel less burned out, have better morale, and be more satisfied with their jobs. Furthermore, people are more likely to trust and rely on technology when they believe it meets their psychological needs, which strengthens the bond between the user and the tool (Saborio, 2023 May). Improving user experience and mental health can have positive effects on society as a whole. Digital platforms that raise awareness about mental health concerns and facilitate access to counselling services, for example, can lessen the stigma attached to mental health problems and increase accessibility to help. Additionally, technology can support a happier, healthier society by promoting pleasant emotional states and lowering stress through well-thoughtout design (Irshad, 2024 March).

So, developing technology that is not just practical and efficient but also emotionally stimulating and conducive to mental health is essential to improving both user experience and mental health.

Using a holistic approach to design, technology is guaranteed to have a beneficial impact on consumers' lives, improving their general well-being as well as their level of happiness with the product. Such a strategy has numerous advantages, from increased mental health and personal fulfilment to wider social effects. The future of digital interactions will be shaped more and more by the convergence of user experience and mental health as technology advances.

2.2.5 Points taken in relation to the whole topic

In the ICT sector, the nexus between counselling and human psychology is critical to improving user experience and fostering mental health. The increasing integration of technology into daily life necessitates a deeper understanding of users' psychological requirements and behaviors in order to build effective systems that promote mental health. Counselling concepts can be used to create digital interfaces that are sympathetic and responsive, which will enhance the user experience. By integrating psychological insights, businesses can create and implement ICT solutions that promote well-being, reduce stress, and raise satisfaction. This tactic benefits both consumers and the general success of digital products by raising user engagement and retention. Ultimately, by combining ICT, psychology, and counselling, more human-centered solutions that priorities mental health can be created, improving the digital world's ability to assist and include all users. Now, let's examine the relationship between the researcher's grants and the topics covered in detail under the aforementioned subheadings.

Prevent burning out on your IT ambitions! Let's start during Mental Health Week by talking about how important it is to put your health first as you begin your career in the tech sector. Without a doubt, the tech industry has the power to change society. It changed our lives, spurred creativity, and opened up exciting career opportunities. It does, however, bring with it a distinct set of challenges. Tech companies are usually considered to have some of the most difficult workplaces to work in. Even while there may be big rewards, tech professionals' mental health may suffer as a result of this strain. By tackling mental health issues in the technology sector According to the Burnout Index, which polled over 32,000 computer workers worldwide, 62% of them feel emotionally and physically exhausted from their jobs' demands. After a workday, 69% of women and 56% of men report feeling exhausted. Of the employees, 2 out of 5 have a significant risk of burnout, and 42% are thinking about leaving their current position. While a UK report by the BIMA Tech Inclusion & Diversity highlights the following critical areas for diversity and inclusion in the

tech workplace improvement: Compared to the national average, stress levels are much greater, with 66% of respondents experiencing difficulties. Anxiety or depression have affected 52% of the responders. 35% of respondents, compared to 22% of respondents overall, believe that their job advancement has been impeded. A sizable percentage of ethnic minorities say they have encountered prejudice. This author cites long hours, tight deadlines, tight deadlines as contributing causes of these adverse conditions. There is concerning research that suggests the work cultures of IT companies are a factor in the mental health issues that employees face. IT workers are probably experiencing a great deal of stress, anxiety, and depression due to the high pressure and demanding nature of their jobs. It is the duty of your employers to make sure that their staff has the time, support, and tools necessary to help you succeed and feel like a valuable team member. Once your business understands what stresses people out, the following tactics can help lessen the effects of stress: Diversity & Inclusion: To encourage creativity and produce a greater variety of viewpoints. An atmosphere at work that is more encouraging and collaborative may result from this. Acknowledgement; Making frequent check-ins to provide assistance and handle any issues. Encourage and support emotional and physical well-being. Having flexible working hours or the ability to change schedules can greatly enhance work-life balance. (Matthews, 2024).

In honor of Mental Health Awareness Week, here is an article. The IT industry was selected due to its ongoing improvements and dynamic economic sector. As was already established, technical professionals deal with three issues. Digital Workers' Mental Health Issues: Mental health is impacted by the work environment, strict deadlines, and stressful assignments. Two out of every five employees questioned had a high risk of burnout, and forty-two percent of them want to leave their position within the next six months. Challenges in Integrating Work and Life: Personal life issues have resulted from long hours and a distant work environment. (After a workday, 69% of women and 56% of men report feeling exhausted and depleted of both physical and emotional vitality.) Regardless of how this article is written, society can develop a tech sector where workers feel appreciated, encouraged, and enabled to realize their full potential, stimulating success and innovation in the rapidly changing tech sector. To promote a culture of resilience, creativity, and success, tech companies need to acknowledge and respond to the particular wellness issues that affect their workers. Tech firms can foster settings where people thrive on a personal and

professional level by putting in place measures to support mental health, prioritize physical wellbeing, and promote work-life integration. (Peters, 2024)

As more identifiable problems: Higher attrition rates: 81% of Gen Zer's and 68% of Millennials have quit their jobs due to mental health issues. This worrying trend emphasizes how important it is for businesses to handle mental health concerns and establish welcoming workplaces in order to keep young talent. Stress and burnout: After work, 56% of IT professionals report experiencing burnout, which is a common problem. Furthermore, a noteworthy 62% of tech workers claim that the demands of their jobs have left them physically and emotionally exhausted. This ongoing fatigue not only damages one's own health but also impedes creativity, productivity, and general job happiness. Implications for DEI: The impact of mental health issues on particular populations is disproportionate in the tech industry. Mental health symptoms are more common in younger workers and historically under-represented groups; respondents who are Millennials and Gen Zers, as well as LGBTQIA+, Black, Latin, and female, are more likely to suffer from mental health problems. Reducing these differences is essential to creating a diverse and inclusive workplace that promotes the wellbeing of all workers. Negative effects on leaders: C-level executives and other leaders in the IT sector deal with mental health concerns, despite the popular misconception that successful leaders are immune to such issues. Their capacity to lead effectively may be impacted by the demanding nature of their roles and the pressure to produce outcomes, which can have a negative impact on their wellbeing. Problems like self-inefficiency, which occurs when leaders experience self-doubt, can negatively influence decision-making, interpersonal interactions, and organizational performance, which in turn impacts the organization's financial success. The reasons for these problems are given: Work methods that are not sustainable, a lack of connection and communication, inadequate resources. They have created a website as a solution to these problems. Let's see what else it does.

At Tek Experts, they are dedicated to putting our workers' mental health first. They do this by supporting diversity and inclusion, delivering wellness programs, offering supportive leadership, putting in place flexible work schedules, and cultivating a happy work environment. They have a large number of women in tech and leadership positions, and our executives actively coach and assist staff members to manage work and personal life. They also give people access to counselling services and resources for mental health. The establishment of a healthy work environment is

contingent upon the core elements of open communication, transparency, and collaboration. "At Tek, we value one another, recognize our strength in unity, and are always learning and developing. We help one other through the difficult and emotionally taxing times that arise at work and in our personal lives. And we have the ability to improve the world by living according to our corporate ideals," says Mark Shafer. Mark is a strong supporter of the EAP program offered to USA Tek Experts workers and is committed to eliminating the stigma associated with seeking treatment for mental health issues. Work methods that are not sustainable, a lack of connection and communication, inadequate resources. (Harrison, 2024)

According to the 2016 OSMI study, there is a markedly higher likelihood of mental illness among those working in the technology sector. It appears that the mental health problem isn't getting any better in the wake of the COVID-19 pandemic and in the larger VUCA (Volatility, Uncertainty, Complexity, Ambiguity) environment. People tend to leap to the newest technical breakthroughs while trying to address a situation. It may seem common sense to create a space where people feel comfortable sharing, especially in light of the recent rise in mental health activism during the COVID-19 pandemic. Even so, "the overall discussion has reduced post-pandemic," and workers are still reluctant to bring up mental health issues in the workplace. Remarkably, according to a Paychex poll, "29% of employees feared that discussion about their mental health issues might affect their promotion" and "54% of employees reported having felt uncomfortable discussing mental health with their supervisors or managers." Furthermore, "there can be a persistent fear that someone will find out and a fear of the consequences" for people who have not revealed their diagnosis. These figures highlight how important it is to create psychologically secure environments where workers feel at ease discussing their experiences or symptoms related to mental health. Companies may set the stage for significant change by creating psychologically safe workplaces, tearing down obstacles to honest communication, and giving leaders the authority to put respect and empathy first. Creating an environment where people feel accepted and encouraged supports long-term resilience in addition to mental health measures. As individuals prosper, the company also prospers. (O'Neill, 2024)

In their study, "IT expert retention through organizational commitment: A Study of Public Sector Information Technology Professionals in Pakistan," Naviq & Bashir made an effort to assess the factors that could encourage organizational commitment among Pakistani IT sector workers. An

uniform questionnaire was used to collect data from nine IT companies. The main finding of the study is that support from supervisors, training and development opportunities, and remuneration are important factors linked to organizational commitment. They contend that IT workers should be seen as individuals with unique needs and goals, such as the achievement of higher levels of responsibility and empowerment, equity and justice, the capacity for learning and innovation, and recognition from peers and management. (Bashir N. , 2015)

The authors of "The Influence of Employee Rewards, Human Resource Policies, and Job Satisfaction on Employee Retention in Vodafone Ghana Limited" made an effort to examine how these factors affected the company's ability to retain employees. The main objective of the study is to look into the connection between employee retention, HR practices, and work happiness. A semi-structured questionnaire with a sample size of 142 organization employees was used to collect the data. The collected data was evaluated using Pearson Chi-square tests and descriptive statistics. The main finding of the research indicated that recognition programs should be put in place instead of just cash prizes. (Ofosuhene, Employability of distance education graduates of a public university in Ghana, 2023)

One industry that has a significant impact on a nation's economy is the IT sector. Here, the employees' mental state is assessed. People who experience poverty and unemployment, as was previously noted, bear the consequences in quiet. Employees were also impacted by the companies' struggles to resume business operations that were suspended during the Covid period. Devastating results for mental health have been mostly caused by long working hours. Consequently, there is a blurring of the lines between personal and professional life, and work-related stress has caused family obligations to be divided. This article asserts that the pertinent parties must act quickly to promote stability. Government agencies need to be aware of their suffering and form partnerships with the businesses to take proactive measures to provide a secure working environment, considerate work schedules, and most importantly, a reliable source of food. (Jyoti Prakash, 2023)

According to this article, in order to keep professionals with professional experience and make employable people in the IT industry, stress-related issues must be successfully resolved for employees. Therefore, reducing stress among employees can be achieved by designing and implementing appropriate stress management programs and making the practice of doing so a ritual

through regular work procedures throughout the organization, as opposed to allowing a lucent and free environment by compromising the fundamental discipline. Additionally, it is suggested that different managerial positions be created in the industry for the employees. Then, considering the improved opportunities inside the same company, fresh IT programmers will be hired and kept in the sector. (M.Preetha, 2023)

2.3 Theoretical Background

2.3.1 User-Centered Design (UCD)

In the counselling industry, User-Centered Design (UCD) approaches are used to provide more successful and customized services by understanding and catering to customers' requirements, preferences, and experiences. It might be difficult to get personal information about IT professionals because many of them work from many places, sometimes even their homes, including foreign institutions and countries. Using the UCD theory is quite helpful in situations like these. Below is a list of some methods related to the UCD hypothesis. Interviews and surveys with clients are directly questioning customers about their needs, expectations, and experiences. This could help counsellors identify what parts of the counselling process clients find simple or challenging. The creation of personas is Extensive profiles of different kinds of clients are made with real data. By utilizing these personas to represent typical clients and their distinct needs, counsellors can more effectively modify their approach to suit various individuals (Norman, 2022).

Charting the client's path from the first point of contact to the conclusion of the counselling process is known as journey mapping. This helps identify the client's areas of discomfort or possible sources of misunderstanding, annoyance, or lack of support. Testing for usability is When it comes to digital tools, like online therapy platforms, this means asking users to evaluate the interface and provide feedback on how easy or difficult it is to use. This ensures that digital technologies utilized in counselling are both effective and user-friendly. Incorporating clients into the process of developing counselling tools or services is known as co-design. Seminars where counsellors and clients work together to produce better experiences could be one example of this (Sylvain Fleury, 2014). Continually gathering client information throughout the counselling process and adapting the services based on the feedback is known as an input loop. This ensures that the services will

always be effective and applicable. Acknowledging clients' thoughts, feelings, and behaviors in a variety of settings is known as empathy mapping. Counsellors can relate to their clients more easily and provide more tailored support as a result. Researchers adopt this theory because it suggests that by using these UCD strategies, counsellors may offer more client-centered services that are better tailored to the unique needs of each individual, which will eventually result in more positive outcomes (Ji-Ye Mao, 2005).

2.3.2 Technology Acceptance Model (TAM)

People's adoption and use of technology can be explained with the help of a framework called the Technology Acceptance Model (TAM). Two factors primarily impact a user's decision to accept or reject a technology, according to TAM. The degree to which a person believes that using a certain technology would increase their productivity or make their life easier is known as their Perceived Usefulness (PU). Perceived Ease of Use (PEOU): PEOU gauges how easy or difficult a user anticipates using a piece of technology. External factors, like system design features or user experience, have an impact on these parameters and, in turn, affect the user's attitude towards technology and desire to utilize it. The concept posits that adopting new technologies is more likely when there is a positive mentality and a high level of perceived utility and usability. When the TAM model is combined with psychology, our understanding of the underlying cognitive and emotional processes that underpin the model's perceived usefulness and usability shifts. Psychology offers insights into how people interact with technology based on their attitudes, beliefs, motivations, and past experiences (Emran Aljarrah, 2016). Cognitive Psychology is TAM and cognitive psychology are related by the concept of mental models, or how people understand and mentally represent a technology. When a user's mental model and the functionality of the technology align well, the likelihood of technology adoption increases. This is a result of the user's perception that technology is simpler to use. Behavior and Motivation is Psychological theories like the Theory of Planned Behavior (TPB) and Self-Determination Theory (SDT) complement TAM by analyzing how extrinsic and intrinsic incentives affect behavior. For example, when a person feels competent and independent when utilizing a technology, they are more likely to perceive it as beneficial and easy to use (K. Worthington, 2021)

Emotional Reactions is Since one's feelings around technology can greatly influence how simple and useful they perceive it to be, emotional psychology is equally relevant in this situation. For instance, a positive initial experience might raise perceived utility, but anxiety over implementing new technology can lower perceived usability. User Experience (UX) and contentment: A user's psychological experience, which encompasses feelings of control and contentment, can also have an impact on their acceptance of technology. Improved pleasure can be linked to enhanced usability and simplicity through improved user experience (Davis, 1989).

In summary, the TAM model's incorporation of psychological ideas results in a deeper understanding of the ways in which users' attitudes, beliefs, emotions, and motives influence the technology they embrace. This integrated approach can provide guidance for the design of more user-friendly technologies that better meet the needs and expectations of users.

2.3.3 Theory of Technology-Mediated Learning (TML)

The field of Technology-Mediated Learning studies how technology can enhance learning, particularly in situations when traditional face-to-face interactions are replaced or supplanted by digital technologies. TML emphasizes on the interaction between technology, the learner, and the educational content in order to understand how technology affects learning outcomes, engagement, and the complete educational experience. The TML paradigm states that technology serves as a mediator between students and educational resources. It is available in many different formats, such as online courses, interactive multimedia, virtual classrooms, and instructional software. The learner's characteristics, the technology's design, and the content being presented are some of the factors that influence TML's effectiveness. Important components of the TML paradigm include technology, learners, content, and interaction (Shield, 2016).

In the IT industry, TML is crucial because skill and knowledge acquisition are constant requirements. Because technology is developing so quickly, IT professionals must always be learning new things. TML enables training solutions that are affordable, flexible, and scalable. For instance, by using online courses, webinars, and virtual labs, IT professionals can learn new programming languages, software tools, or cybersecurity protocols without physically being in a classroom. In an industry where professionals regularly have to choose between fulfilling their duties to their employers and furthering their education, this flexibility is crucial. From a

psychological perspective, TML takes into account the social, emotional, and cognitive aspects of learning. Cognitive psychology is taken into consideration while creating content to ensure that it organically fits with how people perceive information. For instance, multimodal learning theories suggest that combining audio and visual knowledge may enhance comprehension and recall. TML has an emotional impact on engagement and motivation. Enhancing student motivation can be achieved through gamification, interactive elements, and personalized learning pathways that make the learning process more engaging and pertinent. The Theory of Technology-Mediated Learning states that psychological insights are better integrated into instructional content creation and delivery in the IT industry, resulting in learning that is efficient, interesting, and flexible enough to satisfy the demands of contemporary learners (Saurabh Gupta, 2015).

2.4 Previous Studies

A significant study gap, mainly methodological in character, is shown when examining the effects of human psychology and counselling on improving user experience and mental well-being within the ICT business using online technology. Upon doing a thorough literature analysis, it is apparent that although a large number of studies have been carried out in this field, the majority mostly utilize quantitative research methodologies. These studies provide insightful information about quantifiable results and statistical correlations pertaining to user behavior, adoption of technology, and mental health. But they frequently fail to capture the complex, subjective experiences of users, which are essential for a thorough comprehension of the psychological and emotional aspects at play.

Considering the volume of quantitative research conducted, it is evident that the methodological approaches used in this sector are significantly lacking. It becomes clear why qualitative research is necessary in particular. Qualitative research is a perfect technique for exploring the complexities of the human experience since it provides deep insights into the ideas, emotions, and motivations of users. It makes it possible to examine how users engage more intimately with technology, how they view their mental health in relation to ICT use, and how counselling concepts might be successfully incorporated into these tools to support mental health. The decision to focus on a methodological gap, notably by utilizing a qualitative research technique, is motivated by the fact that the majority of the literature currently in publication is heavily biased in favor of quantitative methodologies. Although quantitative research has the potential to find patterns across large

populations and is generally generalizable, its comprehension of the "why" and "how" of these trends is often limited. This is where qualitative research excels since it enables researchers to delve deeply into the actual experiences of customers and uncover insights that cannot be discovered via the use of numbers alone.

This study intends to fill the methodological gap in the literature and provide a more comprehensive knowledge of how psychological and counselling concepts could improve mental health and user experience within the ICT organization through the use of qualitative research. This strategy aims to collect detailed user narratives and intimate insights through the use of tools such as focus groups, in-depth interviews, and case studies. These qualitative observations will complement the existing quantitative findings and offer new perspectives that can direct the development of more user-centered and compassionate technology.

To sum up, the main methodological research gap in this study is that more qualitative research is needed to completely comprehend the complex relationships that exist between ICT, counselling, and human psychology. The goal of the project is to bridge this knowledge gap and offer a more thorough grasp of the ways in which web technologies could be created to enhance and promote user experience and mental health.

2.5 Conclusion

The second chapter of this paper offers a comprehensive review of the literature on how counselling and human psychology could enhance the mental health and user experience of the ICT sector, particularly with relation to online technologies. The chapter opens with an introduction that highlights the importance of integrating psychological concepts and counselling approaches into ICT in order to create user-centric designs that improve mental health. This establishes the foundation for delving into relevant ideas and empirical studies that highlight the convergence of psychology, technology, and therapy.

The theoretical background section covers three main frameworks: User-centered Design (UCD), which focusses on designing systems that priorities users' needs and preferences to ensure intuitive and satisfying interactions; Technology Acceptance Model (TAM), which explains user adoption of technology based on perceived usefulness and ease of use; and Theory of Technology-Mediated Learning (TML), which examines how technology supports learning and knowledge acquisition

while taking cognitive processes in digital interactions into account. When taken as a whole, these theories provide a solid framework for understanding how psychological factors impact user interactions with ICT, guiding the creation of psychologically sound and intuitive technology.

A number of significant subjects are covered in further detail in the empirical review section. It begins with an examination of human psychology, with a focus on behavioral, emotional, and cognitive elements that influence people's interactions with technology. These include motivation, focus, stress, and emotional responses. The role of counselling in promoting mental health is covered in the counselling subchapter, which focusses on techniques and approaches that can be integrated into ICT to offer users supportive experiences. Digital interventions, feedback mechanisms, and sympathetic design are some of these techniques. The next section of the article examines the convergence of human psychology and counselling in the ICT industry, demonstrating how psychological insights and counselling principles can impact web technology design and implementation to create more supportive and empathic digital environments. This means developing interfaces that lessen stress and cognitive load, providing resources for mental health, and being conscious of the emotional states of users. Furthermore, a summary of research findings from multiple studies that show how integrating ICT with psychological and counselling approaches can improve user satisfaction, lower stress, boost engagement, and generally improve mental health outcomes is provided in the section on improving mental health and user experience. These studies show that, in addition to their intended purposes, web technologies can also be aids for enhancing users' mental health.

A comprehensive review of the literature reveals several shortcomings, the most significant of which is the dearth of research on the precise mechanisms by which online technologies could successfully integrate counselling approaches to enhance user experience and promote mental health. While prior research has addressed issues of technology acceptability and user-centered design, there is a paucity of studies on the direct application of psychological counselling concepts within the ICT context to support users' mental health. Furthermore, empirical research is needed to evaluate these integrations' effectiveness in real-world situations while accounting for a range of user demographics and settings. Overall, this chapter establishes a solid foundation for the research by highlighting the need of a human-centered approach in developing online technologies that priorities user happiness and mental health.

Chapter 03. Methodology

3.1 Research Design

With a particular focus on online technologies, this study attempts to investigate how human psychology and counseling might be integrated to improve user experience (UX) and mental health within the Information and Communication Technology (ICT) industry. In order to investigate the psychological mechanisms and counseling approaches that influence users' interactions with web based technology, this study has a predominantly qualitative design. Because it enables a profound, nuanced knowledge of individual experiences, emotions, and psychological reactions—all of which are essential to the research problem-the qualitative technique was selected.

This decision is supported by the nature of the study topics, which seek to determine how psychological knowledge and counseling techniques might enhance the user experiences and mental health outcomes related to web technologies. A qualitative design is most suitable since personal viewpoints and narratives are the most effective way to examine psychological phenomena like stress, anxiety, emotional reactions to digital platforms, cognitive overload, and digital burnout. Understanding the psychological effects of ICT products on users and how to enhance them requires extensive, detailed data, which qualitative research methods-in particular, theme analysis and in-depth interviews-will give.

Additionally, qualitative research makes it possible to gather firsthand information that reflects the complexity of human emotions, perceptions, and the impact of online technology on mental health. These components are essential to comprehending how psychological ideas like cognitive load, emotional design, and mental health counseling may be used to develop digital platforms that support user happiness and emotional well-being. The qualitative approach in this study enables a more comprehensive investigation of the subjective experiences of users in their engagement with ICT tools, as opposed to a quantitative approach, which would concentrate on numerical data and quantifiable results.

3.1.1 Alignment with Research Questions and Hypotheses

Understanding how psychological ideas and counseling methods can be included into ICT design to enhance user experience and mental health is at the heart of the research questions driving this work. Among these inquiries are;

- How can web technology in the ICT sector improve user experience and mental health by using human psychology and counseling techniques?
- What effects do psychological ideas currently have on user experience and how do they affect the way web technologies are designed in the ICT sector?
- Which approaches work best for integrating counseling strategies into web technology design to support users' mental health?

In order to investigate user experiences, perceptions, and emotions when engaging with online technologies, as well as the efficacy of incorporating psychological and counseling approaches into the design process, these inquiries are qualitative in nature. In order to gain a better knowledge of the psychological effects of web-based platforms, the researcher will be able to explore users' emotional responses, cognitive processes, and individual experiences through the use of a qualitative design.

This study attempts to close the gap in the literature by employing a qualitative approach, as the psychological and emotional components of user experience are frequently disregarded or not sufficiently examined. This study's main premise is that by lowering cognitive overload, anxiety, and digital burnout, web technology design that incorporates psychological concepts and counseling techniques can enhance user experience and mental health. This hypothesis is in line with the goals of the study, which are to find psychological strategies that can improve web-based platforms and raise user pleasure and engagement.

3.1.2 Qualitative Approach

This study's qualitative design will be guided by a number of psychological theories and frameworks. These include Emotive Design, which focuses on developing technology that elicits pleasant emotional responses, and Cognitive Load Theory, which investigates how the mental work needed to operate a technology might affect user happiness and stress levels. The investigation of

how web technologies might be developed to lessen user fear and boost emotional involvement will be guided by these psychological frameworks.

The study will make use of counseling psychology procedures, which concentrate on comprehending and meeting people's emotional and psychological needs, in addition to these theoretical frameworks. We'll examine counseling techniques like digital empathy, empathetic feedback, and emotionally supportive interfaces to see how they may be incorporated into web technology design to provide user experiences that are more psychologically supportive.

3.1.3 Rationale for the Design

The necessity to obtain comprehensive, in-depth information about the experiences of ICT users who utilize online technologies on a daily basis further supports the qualitative study design. These experiences are complex and subjective, encompassing not just behavioral and cognitive elements but also emotional reactions that are difficult to measure quantitatively. Through focus groups, case studies, and open-ended interviews, the qualitative method enables the researcher to obtain profound insights that are ideal for examining the subtleties of human psychology in relation to digital technology.

Additionally, as the study develops, the researcher can modify and improve data collection techniques thanks to the flexibility that qualitative research offers. This flexibility is especially crucial in research that examines the complex relationship between technology, psychology, and counseling since new themes may emerge that call for more investigation.

3.1.4 Benefits of Qualitative Research

- Investigation of Psychological Depth: The qualitative method makes it possible to investigate how people react emotionally, psychologically, and cognitively to web technologies. It captures how people feel, see, and react to digital settings, going beyond superficial analysis.
- Understanding User Experience: The researcher can better comprehend users' individual experiences, annoyances, and requirements when utilizing online technologies by conducting in-depth interviews and case studies. Designing ICT tools that are both practical and emotionally uplifting requires this.

- Creation of a Comprehensive Framework: Using the qualitative data, a comprehensive framework for incorporating counseling methods and psychological concepts into ICT design will be created. Future web technology development will be guided by this paradigm, which gives users' mental health and wellbeing first priority.
- Impactful Information: Web developers, UX designers, and mental health specialists can utilize the rich, in-depth information gathered through qualitative approaches to produce actionable insights that will help them build more user-centered, sympathetic, and helpful digital environments.

In conclusion, the study's goals are perfectly aligned with the qualitative research design, which allows for a thorough investigation of the psychological and emotional elements that influence user experience in web-based technologies and offers the flexibility to capture the intricate, subjective nature of these interactions. By employing qualitative methods, the study hopes to produce insightful information that will direct the incorporation of psychological and counseling principles into ICT design, ultimately enhancing user experience and promoting mental health in the digital age.

3.2 Participants or Sample

The study's participants will be chosen from a certain group of people who work in the ICT sector, with an emphasis on those who have both professional and academic background in web technology. The study will specifically focus on senior students and recent graduates of Sri Lanka's University of Vavuniya who are employed in the web technology industry. Because of their theoretical knowledge of ICT and practical web technology skills, this population is well-suited to the research objectives. They are a perfect sample for investigating how human psychology and counseling techniques can improve user experience and mental health in digital contexts.

3.2.1 Characteristics of the Participants

People who have finished or are almost finished with an academic program in information and communication technology (ICT) or similar subjects will make up the majority of the participants. It is anticipated that these people will possess a strong background in user experience (UX) design and web development. In light of the study's particular focus on the

psychological aspects of ICT tools, the participants will also have prior experience using a variety of web platforms for academic or professional purposes, so they will be familiar with the kinds of difficulties that users encounter when interacting with digital environments.

Ten participants in all, including a mix of current senior students and alumni working in the web technology industry, will be recruited for the study. The modest sample size was chosen to enable a thorough qualitative analysis and the collection of in-depth information about the psychological effects of ICT. Furthermore, the sample's targeted structure guarantees that participants will have first-hand knowledge of the psychological factors influencing user engagement with web-based platforms in addition to pertinent technical competence.

3.2.2 Selection Criteria

The following will be the main selection criteria for participants:

- Educational Background: Participants must have earned a degree in information and communications technology (ICT) or a closely related discipline (such as computer science or information systems) or be nearing completion of one. By doing this, it is ensured that participants possess the necessary academic background to comprehend the theoretical and technical facets of web technology and how it interacts with human psychology.
- Professional Experience: Participants must be employed in the online technology industry at the moment, preferably in positions involving web development, user experience (UX) design, or related fields. This guarantees that participants have realworld ICT sector experience, enabling them to offer knowledgeable perspectives on the difficulties customers have when utilizing online technologies.
- Knowledge of ICT Tools: Participants must be accustomed to using web-based technologies on a regular basis, either for academic tasks or in their professional activity. This is crucial to guarantee that participants have a foundational knowledge of the common user experiences, annoyances, and mental health issues related to ICT tool use.
- Willingness to Share Individual Perspectives: Participants should be willing to discuss their personal experiences, including any psychological difficulties they may have

encountered when utilizing web technologies, as well as their ideas about how to incorporate counseling techniques and human psychology into these platforms to enhance user wellbeing.

3.2.3 Sampling Method

Purposive sampling is a non-probability sampling technique that will be used to choose the sample. By using this approach, the researcher can choose participants who have particular traits that are necessary to address the research issues. Purposive sampling is the best option for this study since it guarantees that participants possess the necessary knowledge of both the technical and psychological facets of web technology.

Participants will be contacted by the researcher via the University of Vavuniya, namely through the ICT department, where graduates and students actively work with web technologies. A carefully selected group of senior students and alumni who fit the selection criteria will receive invitations to take part in the study. The study's goals and the value of their opinions in advancing the creation of more psychologically aware online technologies will be explained to participants.

3.2.4 Sample Size

Ten participants will make up the sample size, which is manageable and enables thorough qualitative data collection and analysis. To allow for a thorough examination of unique experiences and viewpoints, the sample size has been kept modest. For qualitative research, when the goal is to obtain rich, deep insights rather than extrapolating results to a broader population, this size is suitable.

3.2.5 Data Collection and Flexibility

The researcher will use flexible data collection techniques because of the participants' academic and professional obligations. In order to accommodate participants who might not be able to meet in person owing to time constraints, some interviews will be performed online using Google Forms, even though in-person interviews will still be the main method of gathering data. Without the pressure of a time-limited interview, the use of Google Forms guarantees that participants can reply whenever it is most convenient for them, giving careful and comprehensive responses. This hybrid strategy ensures that data collecting stays comprehensive and significant while optimizing participation.

3.2.6 Justification for the Sample

Because this sample comprises people with both direct experience in the ICT area and the technical know-how required to comprehend the difficulties of web-based platforms, it is ideal for investigating the junction of psychology, counseling, and web technology. Additionally, this sample gives access to people who are probably familiar with the effects of digital technology use on mental health and can provide insightful information about how psychological concepts and counseling techniques might be successfully incorporated into ICT design. Purposive sampling will be used in the study to guarantee that the information gathered is comprehensive, pertinent, and closely related to the goals and questions of the investigation.

To sum up, the study's participants are carefully chosen to guarantee that the sample possesses the training, experience, and knowledge required to offer profound, pertinent insights into the psychological elements of using online technology. The project will produce high-quality, usable data that can aid in the creation of more psychologically informed ICT products thanks to the mix of in-depth interviews and adaptable data collection techniques.

3.3 Data Collection Methods

The methodical process of obtaining and analyzing data from many sources in order to address research questions, test hypotheses, and assess results is known as data collection in science. It is a crucial step in the research process that ensures the reliability and validity of the conclusions.

The process of gathering data entails employing a variety of methods to gather precise and pertinent information, which may be quantitative or qualitative. Getting knowledge about how human psychology and counselling affect ICT and online technologies' user experience and mental health is the focus of this topic. Thus, in this research, we need talk about qualitative methodology.

The basis for analysis and conclusion-making is this procedure.

3.3.1 Primary data collection

The process of obtaining fresh, original data directly from sources for a particular study goal is known as primary data collection. Observations, experiments, questionnaires, surveys, and interviews are examples of methods. Primary data for this study will be gathered from senior university students and web technology professionals, with an emphasis on how human psychology and counselling affect user experience.

Mostly use Interviews to find out how psychological concepts and counselling strategies are used with web technology in ICT, interview web developers, UX designers, psychologists, and users.

Sometimes use questionnaires and Observations to give people surveys to evaluate how ICT tools affect their mental health and their experiences with them and to track the frustrations, anxiety triggers, and other psychological aspects influencing users' experiences as they interact with web platforms. However within this research mostly usable data collection method is interviews.

3.3.2 Secondary data collection

The process of obtaining information from pre-existing sources as opposed to directly from participants is known as secondary data collecting. This kind of information has already been gathered and is accessible, frequently via books, reports, research papers, government publications, or internet databases. Scholars employ secondary data to bolster their investigation by scrutinizing prior discoveries, recognizing patterns, or furnishing background information for their research enquiries. This approach ensures a deeper and better grasp of the research issue while saving time and money. It is frequently used in conjunction with primary data collection.

Review of the Literature is used to gather information on the applications of psychology and counselling in ICT and web technologies from books, articles, and research papers already in publication. Examine case studies of businesses or initiatives that have effectively incorporated psychological concepts into online design. And also use Online Databases to obtain statistical information and prior studies on mental health in ICT, make use of online databases and repositories.

3.4 Procedures

In order to ensure the study's credibility and alignment with its goals, the procedures section describes the methodical measures employed to perform the research. This study uses a qualitative methodology to examine how web technology design incorporates counseling methods and human psychology. In-depth interviews with chosen participants are used to gather data for the study, and online replies are also used to account for schedule restrictions. In order to preserve uniformity and ethical compliance, specific procedures were adhered to, such as securing informed consent and guaranteeing anonymity. The processes seek to generate dependable and perceptive results that significantly advance the goals of the study by offering a precise, methodical structure.

3.5 Data Analysis

There is enormous potential to improve user experience (UX) and advance mental health at the nexus of psychology and technology. Addressing the psychological and emotional effects of ICT tools has become crucial due to their increasing use in both personal and professional contexts. In order to develop helpful digital environments, this study explores the integration of psychological concepts and counseling procedures into ICT systems. Two major themes come out of the thematic analysis of qualitative data: using ICT tools to actively promote mental health and incorporating psychological concepts into ICT design. These themes highlight the ways in which emotionally intelligent technology might improve user happiness, lower stress levels, and change digital interactions.

Applying Psychological Principles to ICT: In order to design ICT products that satisfy users' emotional and cognitive needs, psychological insights are essential. This area focuses on using emotional design concepts to create ICT environments that encourage participation and serenity. User-centric interfaces and systems that arouse good feelings, lessen irritation, and increase general happiness are the focus of emotional design.

The use of calming settings in digital interfaces is one of the main sub-themes. Participants emphasized the stress-reduction benefits of visual and aural stimuli, including calming music, soft imagery, and soothing hues. A peaceful digital environment can be produced, for instance, by using soft pastel colors or images of nature in user interfaces. "The device's screen can be colored to make the mind feel free," according to one participant, highlighting the significance of careful visual design. Similar to this, features that allow users to choose stress-relieving backgrounds or listen to playlists of ambient music can provide a sensory getaway, especially in situations where pressure is high.

Design-based user engagement is another crucial component. Interface simplification that makes them intuitive and easy to use can greatly increase user engagement. On the other hand, disorganized layouts or harsh images can make users feel more stressed and frustrated. For example, participants observed that although simple and soothing designs had the opposite impact, jarring colors or excessive visual clutter could irritate consumers. "The likelihood of becoming furious rises when a harsh color is displayed on the screen," according to one participant,

highlighting the necessity of designs that are both aesthetically pleasant and operationally supportive.

Through positive reinforcement, motivation also becomes a crucial component in fostering output and contentment. Consistent involvement is promoted by providing rewards, such bonuses or promotions, for reaching predetermined targets. In order to sustain strong morale, participants saw that "production is positively impacted by technician promotions and incentive programs," demonstrating how psychological concepts such as reward systems can be used. This strategy emphasizes the significance of recognizing individual efforts in digital environments in addition to being in line with natural human motivators.

The main takeaway from these findings is that emotionally sensitive design techniques need to be given top priority by ICT developers. Through the integration of soothing imagery, intuitive navigation, and inspirational components, developers can produce solutions that not only serve their intended functions but also promote users' mental health. These tactics can be especially effective in the office, where stress reduction boosts output, and in the classroom, where creating a good digital environment promotes improved learning results.

ICT Tools for Mental Health: With creative features and interventions, ICT tools have the ability to actively support mental health in addition to improving user experience. In order to make wellbeing a fundamental aspect of technology use, this theme investigates how digital systems might include mental health support mechanisms.

The incorporation of relaxing characteristics into ICT tools is among the most interesting subthemes. In order to help consumers manage stress, participants often recommended mindfulness exercises, guided meditation sessions, and relaxing music. A straightforward function like a "mindfulness break" alert, for instance, can serve as a reminder to users to pause their extended screen time and stretch or take a deep breath. Similar to this, gamified relaxation techniques can turn digital tools into active health partners by allowing users to participate in stress-relieving activities like relaxing simulations or virtual puzzles. According to one participant, "creating a space in labs where people can listen to relaxing music" could have a major positive impact on mental health, especially in professional settings.

AI-driven counseling support is another creative strategy. AI-powered solutions can offer tailored advice on how to deal with emotional difficulties or manage stress. For example, catboats or virtual assistants with counseling features can provide consumers with instant access to mental health tools like mood monitors or guided breathing techniques. By enabling real-time intervention, these tools help people deal with emotional distress before it gets out of control. "Counseling options can be suggested directly from the device, allowing users to effectively address their mental health needs," according to participants.

ICT tools can also support workplace mental health programs, fostering cultures that value mental health. Creating specialized counseling departments within businesses, providing stress management classes, and incorporating mental health awareness initiatives into routine training curricula were among the suggestions. Organizations could, for instance, "have a counseling unit to support employees during stressful times," according to one participant. By encouraging a culture of care and making workers feel appreciated and supported, these programs increase retention and productivity.

The success of mental health features depends on their use and adaptability. In order to enable users to customize their experience, participants emphasized the significance of customizing tools to meet specific demands. One commenter, for example, proposed that "there should be tools that give users the freedom to choose how they relax or de-stress." Customizable features empower consumers by giving them a greater sense of control over their mental health journey.

The ramifications of incorporating mental health support into ICT tools are extensive. These strategies can reduce burnout, increase concentration, and boost job satisfaction in the workplace. To assist students in managing the demands of their studies, educational platforms may incorporate mindfulness exercises or relaxation techniques. Additionally, by using technology to normalize conversations around mental health, businesses may help lessen the stigma associated with asking for help.

As a conclusion, The results of this study highlight how incorporating psychological concepts and aspects of mental health into ICT tools can have a profoundly positive impact. Developers may create user-friendly settings that promote engagement and serenity by utilizing emotive design

principles. However, cutting-edge mental health features like AI counseling tools and guided relaxation techniques allow ICT systems to go beyond practicality and actively promote wellbeing.

These strategies have drawbacks, such as the requirement for interdisciplinary cooperation, implementation expenses, and user adaption. But the advantages greatly exceed the drawbacks. In addition to enhancing user experience, companies and developers who give mental health first priority in their ICT solutions establish themselves as leaders in the development of human-centered technology.

Future studies can build on these findings by investigating how they might be applied in a variety of businesses and demographics. By scaling these solutions with cutting-edge technologies like artificial intelligence (AI), their efficacy can be further increased and digital tools can be made to seamlessly meet the cognitive and emotional needs of their users. ICT systems can become strong partners in fostering mental health and enhancing digital connections for everyone by bridging the gap between psychology and technology.

3.6. Validity and Reliability

Validity and reliability in qualitative research guarantee the findings' precision, coherence, and credibility. Specific techniques have been used to demonstrate validity and reliability for this study, which uses thematic analysis to investigate how human psychology and counselling are integrated inside the ICT sector.

Triangulation, which entailed cross-verifying the data using several techniques like in-depth interviews and qualitative surveys, was used to increase validity. This made sure that the themes found reflected the experiences and viewpoints of the participants. A wide range of senior students and ICT specialists at the University of Vavuniya contributed data, which enhanced the data pool and offered a variety of viewpoints. Furthermore, member verification was employed, in which participants checked the transcriptions and preliminary results to ensure that their contributions were accurate.

Triangulation, which entailed cross-verifying the data using several techniques like in-depth interviews and qualitative surveys, was used to increase validity. This made sure that the themes found reflected the experiences and viewpoints of the participants. A wide range of senior students and ICT specialists at the University of Vavuniya contributed data, which enhanced the data pool

and offered a variety of viewpoints. Furthermore, member verification was employed, in which participants checked the transcriptions and preliminary results to ensure that their contributions were accurate.

A systematic approach to thematic analysis preserved reliability. Following the six steps outlined by Braun and Clarke, familiarization was the first step in the data analysis process. Systematic coding was then used to find recurrent patterns. These codes were arranged into possible themes, which were further examined and improved to guarantee coherence and consistency. A transparent audit trail that recorded every stage of the analytic process, including coding choices and theme definitions, was kept up to date in order to further improve reliability.

Tools and Techniques: To strengthen the interpretive process, thematic maps were made to show the relationships between themes and sub-themes. Excel and Navigo were taken into consideration as tools for data management and methodical coding process tracking. The researcher engaged in reflexivity by keeping a reflective notebook to identify and reduce any biases that might affect the analysis.

Statistical Considerations: Descriptive statistics were utilized to provide participant demographics and improve the study's contextual comprehension, despite the fact that the study was mostly qualitative. Together, these actions made guaranteed that the results were reliable, transportable, and consistent in comparable situations.

3.7 Ethical Considerations

Ethical rigor was a priority in conducting this research, given its focus on human psychology and counseling within the ICT industry. Below are the key ethical considerations and measures implemented:

3.7.1 Informed Consent

The goals, techniques, and purpose of the study were all explained to the participants. They received comprehensive consent papers that explained the confidentiality procedures in place, the voluntary nature of their involvement, and their freedom to withdraw at any moment. Before data collection started, written consent was sought to make sure participants understood their role and the scope of the study.

3.7.2 Confidentiality and Anonymity

During analysis and reporting, all data were anonymized to safeguard participant identity. To ensure secrecy, pseudonyms were employed in the final report. Transcripts were cleaned of personal information, and secure data storage procedures-such as password-protected files and limited access to raw data-were adhered to.

3.7.3 Risk Mitigation

Possible psychological dangers to participants were carefully examined because talking about mental health and counselling is delicate. The fact that they might stop participating at any time without facing any repercussions and skip any questions that made them uncomfortable was explained to the participants. Additionally, if taking part in the study caused any distress, resources for professional psychological treatment were made available."

3.7.4 Data Protection

By following ethical guidelines for data management, data integrity and privacy were maintained. The study adhered to institutional data storage policies, guaranteeing the safe preservation of both electronic and physical data. Data will only be kept for as long as is required for analysis, and after the project is finished, it will be destroyed in compliance with ethical standards.

3.7.5 Ethical Approval

The appropriate institutional review board granted ethical clearance for the study after examining the research design, participant recruitment strategies, and data handling procedures to guarantee adherence to moral principles.

Together, these factors made sure the study complied with strict ethical guidelines, protecting the rights and welfare of research participants all the way through.

Chapter 04. Data Analysis

4.1 Introduction

An area of growing interest in the ICT sector is the incorporation of counseling methods and human psychology into web-based technologies. Through thoughtfully created digital platforms, this study seeks to investigate how psychological concepts might improve user experience (UX) and foster mental health. The necessity of taking into account the psychological and emotional effects of ICT tools has increased dramatically with the growing reliance on these tools for both personal and professional purposes. In addition to addressing the advantages and difficulties of psychological theories and counseling procedures in ICT, the data gathered for this study also reveals areas for improvement.

In order to comprehend the lived experiences, viewpoints, and recommendations of participants in the ICT business, this study uses a qualitative methodology. 10 in-depth interviews were used to gather the data, which shows how online technologies can be developed to better suit the cognitive and emotional demands of people. The interviews covered a wide range of topics, including the difficulties in creating psychologically informed platforms, the integration of counseling techniques into technology, and the application of psychological notions to web design. These realizations are essential to developing a thorough grasp of how ICT tools might promote mental health while being both practical and user-focused.

The application of psychological concepts, such as using relaxing colors and relaxation techniques, to increase user pleasure is one of the major themes that emerge from the data. Participants emphasized how design elements, including soothing music and images, might help create digital spaces that are stress-free. These components not only improve platforms' visual appeal but also help users feel less frustrated and anxious when using technology. Additionally, it was seen that adding features like guided guidance and different task options increased user empowerment and engagement.

The possibility of incorporating counseling practices into online technologies is another important topic covered in the interviews. Participants highlighted techniques including encouraging breathing techniques, designing calm spaces, and offering automated counseling

recommendations. Despite the potential of these approaches, issues with cost, complexity of implementation, and user adaptability were noted. This emphasizes how crucial it is to design frameworks that are both effective and user-friendly.

Participants noted a number of psychological issues with the ICT tools available today, such as extended screen time, unintuitive user interfaces, and low user technical proficiency. These elements ultimately impact productivity and mental health by causing stress, cognitive overload, and even physical discomfort. ICT developers can create a more encouraging digital environment by resolving these issues.

The interviews also looked at how ICT technologies, by utilizing human psychology and counseling, might actively promote mental health. Among the suggestions were setting up counseling departments inside businesses, promoting technology-assisted relaxation techniques, and offering stress management training. Participants pointed out that putting such policies into place might greatly improve mental health and raise general job satisfaction in positions involving ICT.

To sum up, this study emphasizes how important psychology is in building web-based platforms and ICT applications. In order to provide practical insights for incorporating human psychology and counseling into the ICT sector, the data analysis will go further into the themes and patterns found in the interviews. By concentrating on these facets, the research aims to produce a roadmap for the development of user-centered solutions that support mental health and improve the digital experience in general.

4.2 Thematic analysis process

A qualitative technique for finding, examining, and summarizing patterns (themes) in data is thematic analysis. It enables researchers to emphasize significant findings pertinent to the study issue by organizing and describing data sets in rich detail. The integration of human psychology and counseling strategies into ICT tools to improve user experience and mental health was investigated in this study using thematic analysis. The methodical procedure used to identify themes from the gathered data and map them with sub-themes and codes, as seen in the thematic map, is described in this section.

4.2.1 Familiarization with the Data

A qualitative technique for finding, examining, and summarizing patterns (themes) in data is thematic analysis. It enables researchers to emphasize significant findings pertinent to the study issue by organizing and describing data sets in rich detail. The integration of human psychology and counseling strategies into ICT tools to improve user experience and mental health was investigated in this study using thematic analysis. The methodical procedure used to identify themes from the gathered data and map them with sub-themes and codes, as seen in the thematic map, is described in this section.

4.2.2 Generating Initial Codes

The next stage was to generate first codes in a methodical manner after becoming acquainted with the material. The process of coding involved locating particular words, concepts, and trends in the interview transcripts. Some examples of useful data segments were "calm colors reduce anger," "stress relief through music," and "difficulty in implementing counseling techniques due to cost." Recurring components were identified through the first coding process and grouped into more general categories including ICT problems, the integration of counseling techniques, and psychological concepts in web design. The development of themes and sub-themes was based on these codes.

4.2.3 Searching for Themes

Potential themes were formed by grouping related codes once the data had been coded. This required investigating underlying meanings and finding connections and commonalities among codes. Themes were arranged in a hierarchical fashion, with overarching themes that included several sub-themes.

For example:

Theme 1: Integrating ICT with Psychological Principles

Sub-themes: stress relief through user-friendly designs, soothing graphics that engage users, and tranquil settings.

Codes such as "Use calm colors," "relaxation music," "stress-free navigation."

Theme 2: Integration of Counseling and ICT Development

Sub-themes: Stress-reduction counseling methods and implementation difficulties.

Codes for: "Breathing exercises," "difficulty focusing due to noise," "cost of implementation."

Theme 3: ICT Tools' Psychological Consequences

Sub-themes: Excessive screen time stress and technical problem dissatisfaction.

Codes for: "Mental fatigue," "frustration from unsaved files," "poor user interfaces."

4.2.4 Reviewing Themes

To make sure they appropriately represented the data, the themes and sub-themes were examined. This entailed determining if the themes matched the goals of the study and were corroborated by the data. By combining overlapping categories and removing superfluous codes, the original themes were improved.

For instance, the codes "mental fatigue from screen time" and "difficulty focusing due to noise" were first placed under different topics before being merged under a more general one that addressed stress brought on by ICT use. The theme of "psychological principles in ICT" also included ideas about user-friendly design and relaxing techniques.

4.2.5 Defining and Naming Themes

To capture their essence, the finalized themes were named and described. This step required creating precise definitions and making sure each theme reflected the meaning of the codes that went with it. This arrangement is reflected in the previously posted thematic map, which lists the primary themes, sub-themes, and associated codes.

4.2.6 Producing the Thematic Map

To provide a visual representation of the data, the themes, sub-themes, and codes are arranged in a thematic map. It demonstrates how the major themes—such as overcoming disadvantages, integrating counseling, and using psychological principles—are connected and based on the results of the interviews. The thematic map that was incorporated into this study is depicted below:

Table 1 . Thematic map

Topic	Themes	Sub themes	Codes
Exploring the Impact of Human Psychology and Counselling in Enhancing User Experience and Mental Well-being. (Within the ICT Industry through Web Technology)	Applying psychological principles to ICT	Creating a relaxing background	Use calm colours and music
			Treat people with kindness
		Motivating technicians	Giving promotions as appropriate
			Giving bonus
	ICT development counselling	Using counselling techniques while working	Conducting awareness program
			Creating opportunities in the company
		There are practical application problems	Missing targets
			difficult to focus the mind
	ICT tools that cause stress	Stress while using electronic devices	Increased screen time
			Not enough technical knowledge
		Increased stress affects the job	Leaving the job
			Relationships are broken
	ICT tools to support mental health	Can use ICT tools to relax	Using relaxation techniques
			Maintain a relaxed background
		Conducting counselling units	Referring to physical units
			Referral to counselling through AI tools

	Electronic and user interface	Providing psychological knowledge to technicians	Conducting awareness programs
			Practice counselling methods in free time
		Training for challenges.	Case studies of role models
			Conducting motivational games

4.2.7 Interpreting the Thematic Map

A systematic framework for analyzing the data and drawing insightful conclusions was offered by the theme map. Every theme and sub-theme was thoroughly examined, with a connection to the study's goals. For example:

- The emphasis on soothing hues and soothing music highlights how psychological concepts can improve user happiness and engagement.
- While resolving implementation issues, the use of counseling techniques like breathing exercises demonstrates how ICT tools can promote mental health. The disadvantages that have been found, such tension and mental exhaustion brought on by extended screen time, highlight areas where ICT tool design needs to be improved.

By methodically grouping the data into significant themes, the thematic analysis approach made it possible to extract rich, in-depth insights from the data. This investigation provides a thorough grasp of the relationship between psychology, counseling, and ICT growth by using a rigorous methodology. The theme map facilitates in-depth investigation and practical suggestions for incorporating psychological concepts into web-based technologies by acting as a guiding framework for the study's later portions.

4.3 Presentation of Themes

The way themes are presented offers an organized examination of the main trends found in the data. Codes and firsthand information from the interviews are used to support each theme's sub

themes. These topics provide a thorough grasp of how human psychology and counseling methods are incorporated into ICT tools, improving user experience (UX) and fostering mental health.

4.3.1 Applying Psychological Principles to ICT

Web-based technologies benefit greatly from the application of psychological concepts, which produce user-centric designs that lower stress and boost engagement. This theme emphasizes how psychological insights are incorporated into ICT tools to enhance user experience.

Sub-Themes and Examples ○

Relaxing Environments

Participants underlined the value of soothing music and muted colors in site design. One person, for example, mentioned that "the device's screen can be colored to make the mind feel free." These components foster calmness and lessen emotional tension. Additional observations included the recommendation to add elements such as fish tanks or soft images to digital areas in order to establish a relaxing atmosphere.

○ User Engagement through Design

Interviewees emphasized that while simple and calming designs boost user happiness, too harsh images or disorganized interfaces can raise dissatisfaction. One participant said, for instance, "The likelihood of becoming furious rises when a harsh color is displayed on the screen. However, that tendency lessens if there is a calming color present. ○ Motivation through Positive Reinforcement

According to the findings, production is positively impacted by technician promotions and incentive programs. According to one participant, "promotions and bonuses can encourage employees to stay involved and produce high-quality work."

4.3.2 ICT Development and Counseling Integration

In order to alleviate stress and promote mental health, this theme looks at how online technologies can be integrated with counseling techniques.

Sub-Themes and Examples:

- Stress-Relief Techniques

Incorporating practical counseling tools like breathing exercises and counting techniques into ICT platforms was recommended by the participants. "You can use breathing techniques to calm the mind when overwhelmed by technology," one person said. It was also advised to engage in relaxation techniques like guided meditation using online resources.

- Challenges in Implementation

Notwithstanding the possible advantages, issues like cost and technical viability were regularly brought up. One participant said, for instance, "Workplace noise makes it hard to concentrate on techniques, and extra expenses could occur."

- Automated Counseling Support

It was thought to be a novel idea to employ AI techniques to provide counseling recommendations. "Counseling options can be suggested directly from the device, allowing users to effectively address their mental health needs," one participant noted.

4.3.3 Psychological Drawbacks of ICT Tools

This issue highlights the psychological effects that modern ICT tools have on its users by identifying the stressors and difficulties they present.

Sub-Themes and Examples: ○

- Stress and Frustration

Technical issues and extended screen time were found to be major stressors. One participant said, "You get mentally and physically exhausted from staring at the device screen all the time." The aggravation of losing unsaved work because of system crashes or power outages was brought up by another respondent.

- Impact on Mental Health

According to the participants, these pressures frequently result in emotional tiredness, burnout, and decreased productivity. According to one respondent, "sitting for extended periods of time and adopting poor posture causes physical discomfort and stress."

- Feedback from Users

Inefficiencies and disappointments are often highlighted in user reviews. For example, one respondent stated, "You complain to the boss when you can't achieve the target, which increases workplace stress."

4.3.4 ICT Tools Supporting Mental Health

By including elements that encourage relaxation and stress management, ICT products offer a great deal of potential to actively support mental health.

Sub-Themes and Examples: ○

Relaxation Features

One suggestion was to incorporate guided approaches and relaxing music into ICT tools. One participant said, "The labs should provide a place to listen to relaxing music." Gamified features could also be added to online platforms to assist people relax while working.

○ **Accessibility and Customization**

The necessity of customized solutions that address the demands of each unique user was underlined by the participants. One respondent emphasized, "There should be tools that give users the freedom to choose how they relax or de-stress."

○ **Workplace Support**

Another recommendation was to support the creation of counseling departments within organizations. "A company should have a counseling unit to support employees during stressful times," one participant said.

4.3.5 Success Indicators and Case Studies

Along with identifying successful implementation examples, the study also looked at how to assess the efficacy of psychologically informed ICT tools.

Sub-Themes and Examples: ○

Effectiveness Indicators

As markers of improved mental health, participants proposed tracking task completion rates and user involvement. "We can see how they spend their free time and whether they come to work with passion," said one respondent. ○ Real-World Examples

A number of interviewers cited effective case studies, including online learning environments that integrate psychological concepts and motivational movies. One participant wrote, for example, "It would be helpful if others had similar knowledge because people who know about counseling techniques use them to reduce stress."

4.3.6 Integration of the Thematic Map

These themes, sub-themes, and codes are comprehensively represented visually in the previously mentioned thematic map. It draws attention to how the insights acquired are interrelated and how each element advances our knowledge of the research topic. The map functions as a useful manual for implementing the results in the creation of practical ICT tools by classifying the data into several themes.

The topics covered in this area offer insightful information about how to incorporate counseling methods and psychological concepts into ICT tools. The results highlight the need for usercentered designs that put mental health first, from addressing psychological issues to creating calming spaces. These themes will guide future ICT innovations for improved user experience and mental health by informing the frameworks and suggestions developed in the following sections.

4.4 Interpretation and Discussion

The study investigates how psychological concepts and counseling methods can be incorporated into ICT tools to improve user experience (UX) and promote mental health. Six interviews were thematically analyzed, yielding several important themes that shed light on how ICT tools can be developed to meet cognitive and emotional needs while reducing stress and boosting engagement.

This section explores the significance of the findings, providing interpretations and their applications.

4.4.1 Psychological Principles in ICT

One important subject in the study was the use of psychological concepts in ICT technologies. The employment of soothing colors, soothing music, and inspirational components greatly improves user pleasure, according to the participants. One participant said, for example, "The device's screen can be colored to make the mind feel free, reducing the tendency to get angry." Likewise, calming music was emphasized as a straightforward yet powerful tool for reducing stress at work.

These findings underscore the importance of emotional design in improving user experience.

Emotional design focuses on creating interfaces and environments that evoke positive feelings and reduce stress. By addressing the cognitive and emotional needs of users, ICT tools can foster higher levels of engagement, satisfaction, and productivity. For example, a calming interface can prevent frustration during prolonged screen use, allowing users to concentrate on tasks without emotional distractions.

By adding aesthetically pleasing and sensory components to their tools, ICT developers can take use of these findings. A more user-centric experience can be produced by including features like mood-based music playlists, interactive relaxation exercises, and customizable themes with calming images. This strategy is particularly pertinent in the workplace, as stress reduction can boost worker performance and retention. Additionally, ICT enterprises can establish themselves as leaders in the provision of mentally supporting technologies by implementing emotional design principles.

4.4.2 Counseling Techniques in ICT

One promising approach to reducing user stress and fostering mental health was the incorporation of counseling skills into ICT products. Breathing techniques, mindfulness exercises, and guided relaxation sessions were commonly cited by participants as useful strategies. "You can use breathing techniques to calm the mind when overwhelmed by technology," one person clarified.

These counseling methods provide consumers quick ways to reduce stress and can be easily included into ICT products. Apps that include guided breathing techniques, for example, can assist

users in refocusing during stressful situations. Using mindfulness reminders, like alerts to stop and take a breath, can also help users adopt better routines.

Accessible mental health therapies can be facilitated by ICT platforms. Developers can offer scalable stress-reduction solutions by integrating counseling functions into digital settings. For instance, workplace solutions might provide relaxation prompts during extended shifts, and e learning platforms could incorporate "mindfulness breaks" for students. By including mental Health practices into routine digital encounters, this integration could normalize them.

Organizations can also work with mental health specialists to make sure these aspects are culturally aware and supported by evidence.

4.4.3 Psychological Drawbacks of ICT Tools

ICT tools have many advantages, but they also have a lot of disadvantages, such as stress and burnout from extended screen time, shoddy interface design, and technological inefficiencies.

These elements were recognized by the participants as significant obstacles to mental health. One participant said, "You get mentally and physically exhausted from staring at the device screen all the time."

Other participants mentioned how frustrating technical malfunctions can be, such losing work because of system crashes or power outages. Some respondents shared instances in which these challenges led to dissatisfaction at work, suggesting that these issues not only reduce output but also fuel emotional exhaustion. These results demonstrate the psychological toll that badly designed ICT products take. Users experience cognitive overload and decreased happiness when they run against problems like confusing navigation or faulty systems. Burnout, which is characterized by exhaustion, disengagement, and decreased performance, can result from prolonged exposure to these stresses.

Designing ICT tools with less cognitive and physical strain must be a top priority for developers and organizations. User discomfort is decreased by features like auto-save capabilities, user friendly navigation systems, and error recovery processes. The physical effects of extended screen time can also be lessened by promoting ergonomic measures, such as encouraging screen breaks

and providing advice on good posture. ICT technologies can improve user productivity and mental health by addressing these issues.

4.4.4 ICT Tools Supporting Mental Health

By integrating features that promote emotional resilience, self-awareness, and relaxation, ICT tools have a great deal of potential to actively improve mental health. Participants cited gamified stress-relieving hobbies, guided meditation applications, and relaxing music as examples of successful techniques. One participant proposed, for example, "Creating a space in the labs where people can listen to relaxing music."

Another major area of focus was workplace interventions, with respondents suggesting things like AI-powered mental health platforms and counseling units. By offering consumers easily available, on-demand support during times of stress, these products can help people incorporate mental health care into their everyday routines.

These results show how ICT technologies are becoming more and more useful in promoting mental health. Organizations can build helpful digital spaces that enable people to manage stress and improve their general quality of life by integrating mental health aspects into their systems. By enabling users to connect with others going through similar struggles and share their experiences, these technologies can help promote a feeling of community and belonging.

Workplaces and educational institutions can be revolutionized by incorporating mental health supporting aspects into ICT tools.

For example:

- Workplace Applications: Adding mindfulness exercises or gamified relaxation methods to team collaboration platforms can boost employee engagement and lessen burnout.
- Educational Settings: To assist students in managing stress during tests or project deadlines, e-learning platforms may incorporate mental health services.

In order to guarantee efficacy, developers must use a user-centered approach, integrating input from many demographics to produce solutions that are accessible and inclusive.

4.4.5 Indicators of Success and Real-World Applications

Participants came up with a number of metrics to gauge how well psychologically informed ICT solutions are working. Metrics including job completion rates, user interaction, and qualitative comments were all part of effective evaluation strategies. For instance, one responder said, "We can see whether they come to work with passion and how they spend their free time."

Examples of successful platforms in the real world included AI counseling systems, guided meditation sessions, and motivating movies. These case studies demonstrate how psychological concepts can be successfully incorporated into ICT applications and how they improve user satisfaction and mental health.

Both quantitative and qualitative methods must be used to assess the effectiveness of these instruments. While qualitative feedback captures the user experience and emotional impact, quantitative measures, such as task performance and usage rates, offer quantifiable insights. When combined, these techniques provide a thorough grasp of how well ICT technologies support mental health.

These success metrics can be used by organizations to continuously improve their ICT solutions.

For example:

- In the workplace: Frequent employee input can be used to pinpoint stressors and improve workplace relaxation elements.
- In the field of education, tracking student satisfaction and engagement can direct enhancements to e-learning systems that better promote mental health.

Organizations can create frameworks that integrate psychological well-being, user satisfaction, and functionality by studying successful implementations.

There is a great chance to improve user experience and promote mental health by incorporating psychological concepts and counseling methods into ICT solutions. The ICT sector may produce tools that are both useful and emotionally uplifting by tackling stressors, adding relaxation features, and utilizing success measures. These results offer a path forward for companies and developers to innovate in ways that put user well-being first, guaranteeing that ICT solutions enhance both personal lives and corporate objectives.

4.5 Challenges in Data Analysis

Due to the nature of the data collection procedure, the participants, and the practical limitations faced, doing data analysis for this study presented a number of difficulties. These difficulties had an impact on the data gathering phase as well as the analysis that followed, necessitating tactical modifications to guarantee the accuracy and comprehensiveness of the results.

4.5.1 Limited Availability of Participants

Senior university interns, instructors, and ICT specialists including trainers and demonstrations were among the study's participants. Many of these people have incredibly hectic schedules that combine personal, professional, and academic obligations. It was difficult to schedule interviews around their busy schedules; frequently, this required several follow-ups and timetable changes.

Some interviews had to be done for shorter periods of time than ideal due to availability constraints, which might have resulted in less thorough responses. Inconsistencies in data collecting forms were also caused by scheduling flexibility; some interviews were conducted in person, while others were conducted online, and some involved written responses. The analysis technique became more complex as a result of these variances, necessitating meticulous standardization to guarantee that the findings were similar for every participant.

4.5.2 Time Constraints

Another major obstacle for the participants and the researcher was time constraints. Participants frequently lacked the time necessary to fully participate in the interview procedure because the study was designed for people with demanding jobs in academia and ICT. In a similar vein, the researcher had to balance data coding, topic identification, and interpretation within a constrained timeframe in order to do the thematic analysis.

There may be gaps in the data since participants may not have been able to elaborate on their answers due to the short interview time. For instance, due to time constraints, some subtle facets of incorporating psychological concepts into ICT tools might not have been thoroughly investigated. Due to the short timetable, the researcher had to choose important topics over in depth investigation, which may have resulted in the loss of important but less obvious ideas.

4.5.3 Practical Challenges during Data Collection

Obstacles also arose from practical concerns during data gathering. Among these were practical challenges like finding peaceful locations for interviews, guaranteeing dependable internet connections for online chats, and handling disruptions during sessions. Additionally, there was variation in the quality of responses due to the participants' varied positions and degrees of technology knowledge. For example, whereas some participants concentrated more on technical issues, others were more conversant with psychological concepts and counseling methods.

Occasionally, these pragmatic difficulties led to data fragmentation, necessitating more work during analysis to fill in the blanks and deduce missing relationships. For instance, interrupted comments occasionally lacked depth, requiring additional clarification or data triangulation with other participants.

4.5.4 Balancing Qualitative Depth with Sample Size

With an emphasis on their distinct viewpoints, the study sought to obtain in-depth qualitative insights from a small number of participants (six interviews). This method presented difficulties with generalizability even though it produced rich, detailed data. Because of the limited sample size, the results were based on the individual experiences of the participants and might not accurately represent more general trends in the ICT sector.

Due to the small sample size, a highly contextual thematic analysis that prioritized depth over breadth was required. To keep the analysis relevant and meaningful, it was necessary to pay close attention to the subtleties in the participants' responses. This, however, also made it more difficult to reach firm conclusions regarding the findings' wider relevance, especially for ICT workers working outside of training and academic settings.

4.5.5 Interpretation of Varied Perspectives

Each of the study's participants, who included lecturers, interns, and ICT trainers, contributed their own viewpoints and experiences. Although the data was enhanced by this diversity, it also made it difficult to combine the replies into cohesive themes. For example, professors who were concerned with student involvement and mental health had different priorities than senior interns who were more focused on developing technical skills.

In order to reconcile these disparate viewpoints, the researcher had to use a flexible and iterative thematic analysis technique. Finding overarching themes that complemented the goals of the study required more time and work, even while this made sure the analysis reflected the intricacy of the data. To keep the analysis consistent, it was also necessary to carefully contextualize the participants' varying levels of comprehension of psychological concepts.

4.5.6 Ethical Considerations

Other difficulties arose from the need to ensure ethical rigor in data collecting and processing. Because the study covered delicate subjects like professional stress and mental health, participants needed to be reassured that their answers would remain private. Careful data treatment was necessary to strike a balance between openness and the requirement to preserve participant anonymity.

It was sometimes challenging to contextualize comments because ethical constraints restricted the capacity to directly link particular ideas to specific participants. For instance, the requirement to anonymize the data limited our ability to comprehend how workplace-specific issues affected responses, which may have limited the scope of some analyses.

4.5.7 Strategies to Address Challenges

Notwithstanding these difficulties, a number of tactics were used to guarantee the validity of the data analysis:

- Flexibility in Data Collection: Participants' hectic lives were accommodated by accommodating their preferences and schedules (e.g., by conducting online interviews or accepting written responses).
- Triangulation: The dependability of the results was increased by addressing gaps and discrepancies in individual responses by cross-referencing data from several participants.
- Iterative Analysis: The analysis was made thorough and contextually accurate by going over the data and honing the themes several times.
- The study was able to maintain its significance in spite of time and budget limitations by concentrating on the most pertinent subjects.

The difficulties in analyzing the data show how difficult it is to carry out qualitative research in fast-paced, high-pressure settings like the ICT sector. From practical difficulties to moral dilemmas, these obstacles necessitated flexible approaches to guarantee the accuracy and comprehensiveness of the results. Although some parts of the research were restricted by these limitations, they also highlighted how crucial it is to be flexible and rigorous when dealing with the reality of data collecting and interpretation. In the end, the knowledge gained from this study offers a useful starting point for additional research into how psychology and counseling might be integrated into ICT tools.

4.6 Conclusion

With an emphasis on their potential to improve user experience (UX) and foster mental health, this study investigated the incorporation of psychological concepts and counseling methods into ICT tools. The significance of user-centered design, the function of counseling in stress management, and the difficulties presented by contemporary ICT tools were among the topics that surfaced from a thematic analysis of the data gathered from six in-depth interviews. The results offer a starting point for creating novel solutions that match digital technology with the psychological requirements of people.

4.6.1 Key Findings

According to the investigation, using psychological concepts like soothing colors, soothing music, and intuitive user interfaces can greatly increase user happiness and lower stress levels. In order to create digital spaces that promote engagement and productivity while also supporting mental health, emotional design is essential. Participants emphasized the necessity for features that meet users' emotional and cognitive needs in addition to their utilitarian needs.

Similar to this, including counseling methods like breathing exercises and mindfulness exercises was thought to be a game-changer for stress management in the ICT sector. According to the study, integrating these methods into ICT tools—either through automated processes or workplace interventions—could offer easily available mental health assistance, particularly for people facing demanding work settings. The psychological disadvantages of modern ICT tools, such as mental exhaustion, annoyance from technical difficulties, and cognitive overload brought on by subpar interface design, were also highlighted in the investigation. In order to overcome these obstacles,

attention must be directed toward user-friendly technologies that lower stress and improve user wellbeing.

4.6.2 Practical Implications

The results have important ramifications for organizations, legislators, and ICT developers. Including psychological considerations in the design process allows developers to produce tools that are both emotionally and functionally supportive. Employers can lower staff fatigue and increase employee satisfaction by incorporating counseling-inspired elements into workplace tools. These insights can be used by educators and policymakers to create policies and training initiatives that give mental health in ICT development first priority. In order to create practical and moral answers, the study also emphasizes the necessity of multidisciplinary cooperation between psychologists, ICT specialists, and business stakeholders. The ICT sector may take the lead in developing solutions that meet users' psychological and emotional demands by cultivating these kinds of collaborations.

4.6.3 Addressing Challenges

The study recognizes the difficulties associated with these advances, including implementation costs, time constraints, and user opposition, notwithstanding their potential. In order to ensure that ICT solutions satisfy a variety of user demands while remaining inclusive and accessible, overcoming these obstacles calls for strategic planning, ongoing input, and iterative changes.

4.6.4 Future Directions

The results provide a number of new study directions. The long-term effects of psychologically informed ICT tools on productivity and mental health may be the subject of future research. While investigating the use of cutting-edge technologies like artificial intelligence (AI) in mental health assistance could improve the scalability and personalization of these tools, increasing the sample size to encompass a wider range of sectors and demographics would yield more comprehensive insights.

4.6.5 Final Thoughts

To sum up, the incorporation of counseling methods and human psychology into ICT tools signifies a paradigm change in the ways that digital technologies can promote mental health and user experience. Developers and organizations can create tools that promote not only productivity but also emotional resilience and mental health by solving the issues with present ICT systems and utilizing the knowledge gathered from this study. By bringing technology progress into line with the basic needs of its users, this all-encompassing strategy has the potential to revolutionize the ICT sector.

Chapter 05. Discussion

5.1 Introduction

The study's results are interpreted in the discussion chapter in light of the goals of the investigation and the body of current literature. The study concentrated on how human psychology and counselling may improve user experience (UX) and foster mental health in the ICT sector by utilizing online technology. The key themes that surfaced from the data are thoroughly examined in this chapter, which also emphasizes their importance and relates them to earlier studies and theoretical frameworks.

5.2 Key Findings and Their Implications

5.2.1 Integration of Psychological Principles in Web Technology

Enhancing UX through the application of psychological concepts, such as emotive design, was one of the main themes. Participants highlighted the use of stress-relieving aural signals, relaxing visual components, and soothing colors, all of which are consistent with theories of cognitive load and emotional design. These features decreased frustration and digital fatigue in addition to increasing user happiness.

According to Norman's (2022) theory of user-centered design (UCD), emotional considerations are crucial to guaranteeing user satisfaction. It is also consistent with the Technology Acceptance Model (TAM), which emphasizes how important perceived enjoyment and ease of use are to the adoption of technology. The findings extend existing frameworks by demonstrating that design features directly influence emotional states and mental well-being, especially in high-stress workplaces like the ICT sector"

5.2.2 Counseling Techniques in ICT Development

The study emphasized the possibility of incorporating counselling methods into online tools. Features including breathing techniques, stress management tools, and guided relaxation were recommended as efficient ways to enhance user mental health. These results show that there is a big chance for ICT developers to directly integrate proactive mental health therapies into digital platforms.

This is consistent with studies on tele therapy and digital mental health tools, which demonstrate that users gain from having instant access to counselling resources built into their work tools. As participants proposed, adding AI-driven mental health support systems could expand the reach of these interventions by providing scalable, real-time mental health assistance.

5.2.3 Addressing Psychological Drawbacks of ICT Tools

The psychological costs of badly designed ICT products, such as elevated stress, cognitive overload, and burnout, were often brought up by participants. This supports earlier research on digital stress and emphasizes how urgent it is to create devices that lessen these impacts. The detrimental effects of ignoring psychological factors in design are highlighted by the participants' experiences with difficult-to-use interfaces, prolonged screen time, and a lack of ergonomic support.

These results are consistent with concepts of cognitive load and decision fatigue, which describe how users' minds and bodies are strained by processing too much information and making decisions all the time. Resolving these issues with user-friendly design and features like error recovery and auto-save could greatly improve user satisfaction.

5.2.4 Framework for Human-Centered Design in ICT

The suggested framework for incorporating human-centered psychological and counselling practices into web technology is one of the study's main outputs. To guarantee that digital tools are both emotionally and cognitively stimulating, the framework places a strong emphasis on iterative feedback loops between developers, psychologists, and end users.

The tenets of human-computer interaction (HCI) and participatory design are echoed in this paradigm, which highlights the necessity of adaptive technology and ongoing user input. It also emphasizes how solutions that put mental health first could be developed through cooperation between the ICT sector and mental health specialists.

5.3 Practical Implications

The report offers the ICT sector a number of useful insights, including:

Improving User Experience: By integrating psychological concepts into UX design, users may become less frustrated and more satisfied.

Promoting Mental Health: By incorporating counselling methods into ICT tools, consumers can get stress-reduction tools right away.

Reducing Digital Fatigue:

By addressing cognitive overload and decision fatigue, helpful features and streamlined interfaces can improve wellbeing and productivity.

These ramifications imply that ICT firms can obtain a competitive advantage by creating technologies that not only satisfy practical requirements but also promote the mental health of users.

5.4 Limitations and Future Research

Even though this study offers insightful information, it's critical to recognize its limits. The findings' generalizability is constrained by the limited sample size and qualitative methodology. By using mixed-methods approaches to test and extend the findings and including larger, more diverse populations, future research could build on this study.

Future research might also examine the long-term effects of psychologically informed ICT tools on productivity and mental health, offering a more comprehensive knowledge of their efficacy in practical contexts.

5.5 Conclusion

The study's conclusions highlight how important human psychology and counselling will be in influencing web technologies in the future. The ICT sector can create solutions that improve user experience and encourage better digital environments by putting user well-being and mental health first. This conversation provides a roadmap for upcoming advancements in the area while highlighting the transformative potential of incorporating psychological concepts and counselling approaches into ICT development.

Chapter 07. Appendices

7.1 Interview Protocol

7.1.1 Interview Protocol 1

Table 2 . Protocol 1

Date of the interview	November 15	Place of interview	Through telephone call	Protocol No	01
Starting time	3.00 pm	Ending time	3.30 pm	Job title of Intervener	ICT company programmer

□ In the ICT industry, how are psychological ideas used to web-based technologies

1. Which psychological concepts are most frequently applied to web design?

Colors that make the mind feel free can be used for the screen of the device

2. In what ways do these principles enhance customer happiness or engagement?

It feels uncomfortable when a harsh color is on the screen. Then, if there is any problem in mind, the possibility of getting angry increases. But if there is a relaxing color on the screen, I think that the tendency to get angry will decrease

3. Are there any particular instances of effective ICT implementation?

When you are stressed or bored during working time, you can relax by playing a game on the same device.

□ How can web technology development incorporate counselling techniques

4. Which counselling techniques can be modified for online platforms? Breathing techniques, countering techniques

5. How may these methods help those who are stressed out by technology?

You can do things like this when you are stressed. You can take a ring to work and count the beads when you are stressed. Then the problem can be forgotten because the mind is focused on it

6. What difficulties come up when incorporating counselling techniques into designs? It can be difficult to focus on techniques because of the noise in the place

□ From a psychological standpoint, what are the drawbacks of ICT tools and web platforms

7. What features of ICT tools cause users to feel stressed or frustrated?

Looking at the device screen all the time makes you mentally and physically tired

8. What effects do these deficiencies have on mental health?

Using the wrong posture and using the screen for a long time causes physical discomfort.

Then it will not be possible to go to the relevant targets. Stress is caused by these reasons

9. Which user reviews draw attention to these issues?

When you can't achieve the target, you complain to the boss

□ How can a framework incorporate counselling and human-centered psychology with ICT

10. How can counseling ideas be used in ICT?

The working environment should be made relaxing

11. How can human psychology improve ICT tools?

You have to ask others what you don't know. He wants to work honestly. Then give yourself advice and solve the problem without doubt

12. How can ICT tools support mental health?

An opportunity to listen to relaxation music should be created in the labs. Currently, the use of headsets in labs is not enough

□ How well do online technologies with psychological knowledge promote mental health

13. How are these technologies seen by users?

People who are less stressed are aware of this

14. What indicators may be used to gauge their effect on mental health?

Various challenges are given and it is observed whether they are successfully completed

15. Are there any particular case studies that demonstrate success?

People who know about counseling techniques use them to reduce stress. It would be good if others had the same knowledge

7.1.2 Interview Protocol 2

Table 3 . Protocol 2

Date of the interview	November 15	Place of interview	Through telephone call	Protocol No	02
Starting time	3.00 pm	Ending time	3.30 pm	Job title of Intervener	ICT company programmer

□ In the ICT industry, how are psychological ideas used to web-based technologies

1. Which psychological concepts are most frequently applied to web design?

You can use relaxation music while working

2. In what ways do these principles enhance customer happiness or engagement? Stress is reduced. I like to work
3. Are there any particular instances of effective ICT implementation?

There are various options to do one task. For example, sites like canva and figma are used to make a poster. Then you can choose one thing you like from among many. Its freedom

□ How can web technology development incorporate counselling techniques

4. Which counselling techniques can be modified for online platforms?

Counseling options are suggested from the device itself

5. How may these methods help those who are stressed out by technology?

The programmer should have an awareness that those who have problems can use counseling to get a solution. Most of the time there is no time to spend on those things. Therefore, it would be good if the device could be used to raise awareness about it. A person with a problem can use this method even if he cannot diagnose it himself

6. What difficulties come up when incorporating counselling techniques into designs?

An additional cost may be incurred

□ From a psychological standpoint, what are the drawbacks of ICT tools and web platforms

7. What features of ICT tools cause users to feel stressed or frustrated?

The time to complete the target cannot be decided in advance

8. What effects do these deficiencies have on mental health?

When a code goes wrong, it's time to fix it. Then the time to complete the target increases.

When new work comes, I can't do it all and get stressed

9. Which user reviews draw attention to these issues?

You can even leave the job

□ How can a framework incorporate counselling and human-centered psychology with ICT

10. How can counseling ideas be used in ICT? A company should have a counseling unit

11. How can human psychology improve ICT tools?

Counseling awareness sessions can be held in organization meetings

12. How can ICT tools support mental health?

Technology has advanced enough to hold conference sessions

□ How well do online technologies with psychological knowledge promote mental health

13. How are these technologies seen by users?

Those who work well and go for promotions

14. What indicators may be used to gauge their effect on mental health?

We can see how he spends his free time

15. Are there any particular case studies that demonstrate success? We can watch the motivation video of such people on YouTube

7.1.3 Interview Protocol 3

Table 4 . Protocol 3

Date of the interview	November 17	Place of interview	In Campus	Protocol No	03
Starting time	9.00 am	Ending time	9.40 pm	Job title of Intervener	ICT lecturer

□ In the ICT industry, how are psychological ideas used to web-based technologies

1. Which psychological concepts are most frequently applied to web design?

When scheduling the lecturer time table, only a limited amount of time is allocated to one subject

2. In what ways do these principles enhance customer happiness or engagement?

Since they only have limited time for one subject, they listen eagerly and understand the subject with interest

3. Are there any particular instances of effective ICT implementation?

It has been seen from experience that as the lecture time increases, the mentality of the children becomes distant from the study

□ How can web technology development incorporate counselling techniques

4. Which counselling techniques can be modified for online platforms?

Communicating daily information with students when they feel bored

5. How may these methods help those who are stressed out by technology?

After studying for a long time, this kind of discussion relaxes. Sometimes, personal problems may come to the mind of a student even while studying. When talking freely with someone, if there is a problem in the mind, it will be revealed automatically. So you can study freely after that

6. What difficulties come up when incorporating counselling techniques into designs?

After a long break, the attention given to the lesson may go to another direction and forget the things learned in the beginning. Then you have to go back from the beginning, so the teaching time increases

□ From a psychological standpoint, what are the drawbacks of ICT tools and web platforms

7. What features of ICT tools cause users to feel stressed or frustrated?

Power cuts happen while using the computer. If there are files that cannot be saved, you have to create the file from scratch

8. What effects do these deficiencies have on mental health?

When serious projects are canceled in this way, people get stressed

9. Which user reviews draw attention to these issues?

According to the syllabus, the lecturer's rate will be reduced when it is not possible to conduct the lectures in the scheduled time

□ How can a framework incorporate counselling and human-centered psychology with ICT

10. How can counseling ideas be used in ICT?

As well as getting counseling help when they need it, students are also guided for counseling when needed.

11. How can human psychology improve ICT tools?

When you see it, you have to keep the surroundings mild so that the mind does not get confused

12. How can ICT tools support mental health?

Providing awareness about relaxation from e-learning platform

□ How well do online technologies with psychological knowledge promote mental health

13. How are these technologies seen by users?

Being able to see the teachers who teach in Relax and finish the syllabus on time

14. What indicators may be used to gauge their effect on mental health?

If the children get bored with the teacher and the subject, it is the teacher's fault

15. Are there any particular case studies that demonstrate success?

Studying talented people who do other jobs while teaching

7.1.4 Interview Protocol 4

Table 5 . Protocol 4

Date of the interview	November 17	Place of interview	In Campus	Protocol No	04
Starting time	10.00 am	Ending time	11.00 pm	Job title of Intervener	Demo in university ICT lab

□ In the ICT industry, how are psychological ideas used to web-based technologies

1. Which psychological concepts are most frequently applied to web design?

Studying talented people who do other jobs while teaching

2. In what ways do these principles enhance customer happiness or engagement?

Anyone can easily use the lab and if a device breaks, it can be easily repaired

3. Are there any particular instances of effective ICT implementation?

Devices are connected to each other and there is a separate group to guide those who use computers

□ How can web technology development incorporate counselling techniques

4. Which counselling techniques can be modified for online platforms?

Knowing the techniques of how to practice patience

5. How may these methods help those who are stressed out by technology?

When they don't know how to use the computer or lab and have to teach each other repeatedly, the work may increase and stress may occur.

6. What difficulties come up when incorporating counselling techniques into designs?

Busyness causes problems in personal life and stress

□ From a psychological standpoint, what are the drawbacks of ICT tools and web platforms

7. What features of ICT tools cause users to feel stressed or frustrated?

Repairing computers

8. What effects do these deficiencies have on mental health?

Due to the lack of technical knowledge of all the technical officers, it is difficult to complete the work within a specified time

9. Which user reviews draw attention to these issues?

If there is any damage to the device, it is a disadvantage

□ How can a framework incorporate counselling and human-centered psychology with ICT

10. How can counseling ideas be used in ICT?

If a problem comes to mind, they try to solve it alone. If not, try to get advice from a friend.
But if it is not possible, consult a counselor and solve the problem

11. How can human psychology improve ICT tools?

When we see it, we create a peaceful environment so that the mind does not wander

12. How can ICT tools support mental health?

Using relaxation methods on social media

□ How well do online technologies with psychological knowledge promote mental health

13. How are these technologies seen by users?

Those who can successfully complete several tasks alone

14. What indicators may be used to gauge their effect on mental health?

Increase the tank more and observe their reactions

15. Are there any particular case studies that demonstrate success?

Practice things you can do alone to relax.

7.1.5 Interview Protocol 5

Table 6 . Protocol 5

Date of the interview	November 18	Place of interview	In Campus	Protocol No	05
Starting time	3.30 am	Ending time	4.10 pm	Job title of Intervener	Call Center part time job (University senior)

□ In the ICT industry, how are psychological ideas used to web-based technologies

1. Which psychological concepts are most frequently applied to web design?

Giving an interval giving promotions

2. In what ways do these principles enhance customer happiness or engagement?

You can get physical and mental rest while taking interval. For that, you can do things like playing games and listening to songs

3. Are there any particular instances of effective ICT implementation?

The government has introduced fixed working hours

□ How can web technology development incorporate counselling techniques

4. Which counselling techniques can be modified for online platforms?

Relaxation methods

5. How may these methods help those who are stressed out by technology?

There are ways to relax by using it alone. You can develop your mind and become successful on your own

6. What difficulties come up when incorporating counselling techniques into designs?

There are difficulties in practicing that Crum. There is not much space to do a complete relaxation process

□ From a psychological standpoint, what are the drawbacks of ICT tools and web platforms

7. What features of ICT tools cause users to feel stressed or frustrated?

Not knowing all languages properly

8. What effects do these deficiencies have on mental health?

Not being able to express their opinions properly and not being able to ask questions and get solutions can make the person stressed.

9. Which user reviews draw attention to these issues?

Not being able to utilize the full potential of the person is a disadvantage

□ How can a framework incorporate counselling and human-centered psychology with ICT

10. How can counseling ideas be used in ICT?

If I understand that a client has a problem, I will help with words

11. How can human psychology improve ICT tools?

Depending on the job I do, technical errors and connection issues are common. Sometimes my tone of voice to the client changes depending on my busyness and mental state. But that's a mistake

12. How can ICT tools support mental health?

If you need to check the quality of the service provided, there is an option called recording so that anyone can listen to the tapes and solve the problems.

□ How well do online technologies with psychological knowledge promote mental health

13. How are these technologies seen by users?

You can notice that a person is away from people and isolated in stress

14. What indicators may be used to gauge their effect on mental health?

Come to work with passion, present new ideas, go for promotions easily

15. Are there any particular case studies that demonstrate success?

The head of the call center is a person who started working as a low-level employee and worked his way up step by step

7.1.6 Interview Protocol 6

Table 7 . Protocol 6

Date of the interview	November 18	Place of interview	In Campus	Protocol No	06
Starting time	3.00 pm	Ending time	4.00 pm	Job title of Intervener	3 rd year senior

□ In the ICT industry, how are psychological ideas used to web-based technologies

1. Which psychological concepts are most frequently applied to web design?

Using relaxation techniques and meditation

2. In what ways do these principles enhance customer happiness or engagement?

Even though electronic devices help us in our work, they are not user friendly. Therefore, stress can occur when dealing for a long time. Sometimes it is impossible to relax without the help of others

3. Are there any particular instances of effective ICT implementation?

Simple relaxation techniques can be used in the lab

□ How can web technology development incorporate counselling techniques

4. Which counselling techniques can be modified for online platforms?

Use of gentle colors for the eyes, maintaining fish tanks, organizing and participating in various festivals.

5. How may these methods help those who are stressed out by technology?

Due to the use of these, attention is diverted and problems are forgotten. New friendships are made

6. What difficulties come up when incorporating counselling techniques into designs?

Difficulty in turning freely to relaxation methods

□ From a psychological standpoint, what are the drawbacks of ICT tools and web platforms

7. What features of ICT tools cause users to feel stressed or frustrated?

Problems arise when theoretical knowledge has to be used in practice

8. What effects do these deficiencies have on mental health?

Although the theory is a concept, practical knowledge is needed to use that knowledge in the industry. While learning theory with a group in a lab, in the industry, the individual has to show his abilities alone. Therefore knowledge and practical training is essential

9. Which user reviews draw attention to these issues?

A person's stress can come out as an impulse from a loved one or a close family member

□ How can a framework incorporate counselling and human-centered psychology with ICT

10. How can counseling ideas be used in ICT?

If he is unable to solve his problems alone, he can get the help of another person who has more knowledge and experience than him.

11. How can human psychology improve ICT tools?

Making up one's mind to be strong enough to face pressing problems before they arise

12. How can ICT tools support mental health?

There is an opportunity to choose a job that suits him and he likes. You can quit after working for a while

□ How well do online technologies with psychological knowledge promote mental health

13. How are these technologies seen by users?

There are many friends and academics are also good. Good at everything

14. What indicators may be used to gauge their effect on mental health?

Increasing challenge and responsibilities and observing their behavior. Then you can know how they face the challenges and what mind relaxation techniques they use.

15. Are there any particular case studies that demonstrate success?

Student prefects in schools, batch reps on campus, and leaders in community organizations are like this
